**Usage**

```
multiedit(x, class, k = 1, V = 3, I = 5, trace = TRUE)
```

**Arguments**

x	matrix of training set.
class	vector of classification of training set.
k	number of neighbours used in k-NN.
V	divide training set into V parts.
I	number of null passes before quitting.
trace	logical for statistics at each pass.

**Value**

Index vector of cases to be retained.

olvq1

*Optimized Learning Vector Quantization 1***Description**

Moves examples in a codebook to better represent the training set.

**Usage**

```
olvq1(x, cl, codebk, niter = 40 * nrow(codebk$x), alpha = 0.3)
```

**Arguments**

x	a matrix or data frame of examples
cl	a vector or factor of classifications for the examples
codebk	a codebook
niter	number of iterations
alpha	constant for training

**Details**

Selects `niter` examples at random with replacement, and adjusts the nearest example in the codebook for each.

**Value**

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

reduce.nn

*Reduce Training Set for a k-NN Classifier*

---

**Description**

Reduce training set for a k-NN classifier. Used after condense.

**Usage**

```
reduce.nn(train, ind, class)
```

**Arguments**

train	matrix for training set
ind	Initial list of members of the training set (from condense).
class	vector of classifications for test set

**Details**

All the members of the training set are tried in random order. Any which when dropped do not cause any members of the training set to be wrongly classified are dropped.

**Value**

Index vector of cases to be retained.

SOM

*Self-Organizing Maps: Online Algorithm***Description**

Kohonen's Self-Organizing Maps are a crude form of multidimensional scaling.

**Usage**

```
SOM(data, grid = somgrid(), rlen = 10000, alpha, radii, init)
```

**Arguments**

<code>data</code>	a matrix or data frame of observations, scaled so that Euclidean distance is appropriate.
<code>grid</code>	A grid for the representatives: see <code>somgrid</code> .
<code>rlen</code>	the number of updates: used only in the defaults for <code>alpha</code> and <code>radii</code> .
<code>alpha</code>	the amount of change: one update is done for each element of <code>alpha</code> . Default is to decline linearly from 0.05 to 0 over <code>rlen</code> updates.
<code>radii</code>	the radii of the neighbourhood to be used for each update: must be the same length as <code>alpha</code> . Default is to decline linearly from 4 to 1 over <code>rlen</code> updates.
<code>init</code>	the initial representatives. If missing, chosen (without replacement) randomly from <code>data</code> .

**Details**

`alpha` and `radii` can also be lists, in which case each component is used in turn, allowing two- or more phase training.

**Value**

An object of class "SOM" with components

<code>grid</code>	the grid, an object of class "somgrid".
<code>codes</code>	a matrix of representatives.

plot(crabs.som2)
```

---

somgrid

*Plot SOM Fits*

---

## Description

Plotting functions for SOM results.

## Usage

```
somgrid(xdim = 8, ydim = 6, topo = c("rectangular", "hexagonal"))

## S3 method for class 'somgrid':
plot(x, type = "p", ...)

## S3 method for class 'SOM':
plot(x, ...)
```

## Arguments

`xdim`, `ydim` dimensions of the grid

`topo` the topology of the grid.

`x` an object inheriting from class "somgrid" or "SOM".

`type`, `...` graphical parameters.

**Details**

The class "somgrid" records the coordinates of the grid to be used for (batch or on-line) SOM: this has a plot method.

The plot method for class "SOM" plots a [stars](#) plot of the representative at each grid point.

**Value**

For somgrid, an object of class "somgrid", a list with components

pts                    a two-column matrix giving locations for the grid points.  
xdim, ydim, topo        as in the arguments to somgrid.

## Chapter 15

# The `cluster` package

---

`agnes`

*Agglomerative Nesting (Hierarchical Clustering)*

---

### Description

Computes agglomerative hierarchical clustering of the dataset.

### Usage

```
agnes(x, diss = inherits(x, "dist"), metric = "euclidean",
      stand = FALSE, method = "average", par.method,
      keep.diss = n < 100, keep.data = !diss)
```

### Arguments

<code>x</code>	<p>data matrix or data frame, or dissimilarity matrix, depending on the value of the <code>diss</code> argument.</p> <p>In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed.</p> <p>In case of a dissimilarity matrix, <code>x</code> is typically the output of <code>daisy</code> or <code>dist</code>. Also a vector with length <math>n*(n-1)/2</math> is allowed (where <code>n</code> is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.</p>
<code>diss</code>	<p>logical flag: if TRUE (default for <code>dist</code> or <code>dissimilarity</code> objects), then <code>x</code> is assumed to be a dissimilarity matrix. If FALSE, then <code>x</code> is treated as a matrix of observations by variables.</p>
<code>metric</code>	<p>character string specifying the metric to be used for calculating dissimilarities between observations. The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored.</p>
<code>stand</code>	<p>logical flag: if TRUE, then the measurements in <code>x</code> are standardized before calculating the dissimilarities. Measurements are standardized for each variable</p>

	(column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation. If $x$ is already a dissimilarity matrix, then this argument will be ignored.
<code>method</code>	character string defining the clustering method. The six methods implemented are "average" ([unweighted pair-]group average method, UPGMA), "single" (single linkage), "complete" (complete linkage), "ward" (Ward's method), "weighted" (weighted average linkage) and its generalization "flexible" which uses (a constant version of) the Lance-Williams formula and the <code>par.method</code> argument. Default is "average".
<code>par.method</code>	if <code>method == "flexible"</code> , numeric vector of length 1, 3, or 4, see in the details section.
<code>keep.diss</code> , <code>keep.data</code>	logicals indicating if the dissimilarities and/or input data $x$ should be kept in the result. Setting these to <code>FALSE</code> can give much smaller results and hence even save memory allocation <i>time</i> .

## Details

`agnes` is fully described in chapter 5 of Kaufman and Rousseeuw (1990). Compared to other agglomerative clustering methods such as `hclust`, `agnes` has the following features: (a) it yields the agglomerative coefficient (see `agnes.object`) which measures the amount of clustering structure found; and (b) apart from the usual tree it also provides the banner, a novel graphical display (see `plot.agnes`).

The `agnes`-algorithm constructs a hierarchy of clusterings.

At first, each observation is a small cluster by itself. Clusters are merged until only one large cluster remains which contains all the observations. At each stage the two *nearest* clusters are combined to form one larger cluster.

For `method="average"`, the distance between two clusters is the average of the dissimilarities between the points in one cluster and the points in the other cluster.

In `method="single"`, we use the smallest dissimilarity between a point in the first cluster and a point in the second cluster (nearest neighbor method).

When `method="complete"`, we use the largest dissimilarity between a point in the first cluster and a point in the second cluster (furthest neighbor method).

The `method = "flexible"` allows (and requires) more details: The Lance-Williams formula specifies how dissimilarities are computed when clusters are agglomerated (equation (32) in K.&R., p.237). If clusters  $C_1$  and  $C_2$  are agglomerated into a new cluster, the dissimilarity between their union and another cluster  $Q$  is given by

$$D(C_1 \cup C_2, Q) = \alpha_1 * D(C_1, Q) + \alpha_2 * D(C_2, Q) + \beta * D(C_1, C_2) + \gamma * |D(C_1, Q) - D(C_2, Q)|,$$

where the four coefficients  $(\alpha_1, \alpha_2, \beta, \gamma)$  are specified by the vector `par.method`:

If `par.method` is of length 1, say  $= \alpha$ , `par.method` is extended to give the "Flexible Strategy" (K. & R., p.236 f) with Lance-Williams coefficients  $(\alpha_1 = \alpha_2 = \alpha, \beta = 1 - 2\alpha, \gamma = 0)$ .

If of length 3,  $\gamma = 0$  is used.

**Care** and expertise is probably needed when using `method = "flexible"` particularly for the case when `par.method` is specified of longer length than one. The *weighted average* (`method="weighted"`) is the same as `method="flexible"`, `par.method = 0.5`.

## Value

an object of class "agnes" representing the clustering. See `agnes.object` for details.

## BACKGROUND

Cluster analysis divides a dataset into groups (clusters) of observations that are similar to each other.

**Hierarchical methods** like `agnes`, `diana`, and `mona` construct a hierarchy of clusterings, with the number of clusters ranging from one to the number of observations.

**Partitioning methods** like `pam`, `clara`, and `fanny` require that the number of clusters be given by the user.

plot(agnS)
par(op)

data(agriculture)
## Plot similar to Figure 7 in ref
## Not run: plot(agnes(agriculture), ask = TRUE)
```

## Description

The objects of class "agnes" represent an agglomerative hierarchical clustering of a dataset.

**Value**

A legitimate `agnes` object is a list with the following components:

<code>order</code>	a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.
<code>order.lab</code>	a vector similar to <code>order</code> , but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled.
<code>height</code>	a vector with the distances between merging clusters at the successive stages.
<code>ac</code>	the agglomerative coefficient, measuring the clustering structure of the dataset. For each observation $i$ , denote by $m(i)$ its dissimilarity to the first cluster it is merged with, divided by the dissimilarity of the merger in the final step of the algorithm. The <code>ac</code> is the average of all $1 - m(i)$ . It can also be seen as the average width (or the percentage filled) of the banner plot. Because <code>ac</code> grows with the number of observations, this measure should not be used to compare datasets of very different sizes.
<code>merge</code>	an $(n-1)$ by 2 matrix, where $n$ is the number of observations. Row $i$ of <code>merge</code> describes the merging of clusters at step $i$ of the clustering. If a number $j$ in the row is negative, then the single observation $ j $ is merged at this stage. If $j$ is positive, then the merger is with the cluster formed at stage $j$ of the algorithm.
<code>diss</code>	an object of class "dissimilarity" (see <a href="#">dissimilarity.object</a> ), representing the total dissimilarity matrix of the dataset.
<code>data</code>	a matrix containing the original or standardized measurements, depending on the <code>stand</code> option of the function <code>agnes</code> . If a dissimilarity matrix was given as input structure, then this component is not available.

**GENERATION**

This class of objects is returned from [agnes](#).

**METHODS**

The "agnes" class has methods for the following generic functions: `print`, `summary`, `plot`.

**INHERITANCE**

The class "agnes" inherits from "twins". Therefore, the generic functions [pltree](#) and [as.hclust](#) are available for agnes objects. After applying `as.hclust()`, all *its* methods are available, of course.

**See Also**

---

`agriculture`*European Union Agricultural Workforces*

---

### Description

Gross National Product (GNP) per capita and percentage of the population working in agriculture for each country belonging to the European Union in 1993.

### Usage

```
data(agriculture)
```

### Format

A data frame with 12 observations on 2 variables:

```
  [,1] x numeric per capita GNP
  [,2] y numeric percentage in agriculture
```

The row names of the data frame indicate the countries.

### Details

The data seem to show two clusters, the “more agricultural” one consisting of Greece, Portugal, Spain, and Ireland.

### Source

Eurostat (European Statistical Agency, 1994): *Cijfers en feiten: Een statistisch portret van de Europese Unie*.

## Not run: plot(agnes(agriculture), ask = TRUE)

## Plot similar to Figure 8 in Struyf et al (1996)
## Not run: plot(diana(agriculture), ask = TRUE)
```

---

animals

*Attributes of Animals*

---

### Description

This data set considers 6 binary attributes for 20 animals.

### Usage

```
data(animals)
```

### Format

A data frame with 20 observations on 6 variables:

[ , 1]	war	warm-blooded
[ , 2]	fly	can fly
[ , 3]	ver	vertebrate
[ , 4]	end	endangered
[ , 5]	gro	live in groups
[ , 6]	hai	have hair

All variables are encoded as 1 = 'no', 2 = 'yes'.

### Details

This dataset is useful for illustrating monothetic (only a single variable is used for each split) hierarchical clustering.

### Source

Leonard Kaufman and Peter J. Rousseeuw (1990): *Finding Groups in Data* (pp 297ff). New York: Wiley.

### References

Anja Struyf, Mia Hubert & Peter J. Rousseeuw (1996): Clustering in an Object-Oriented Environment. *Journal of Statistical Software*, **1**. <http://www.stat.ucla.edu/journals/jss/>

### Examples

```
data(animals)
apply(animals, 2, table) # simple overview
```

```

ma <- mona(animals)
ma
## Plot similar to Figure 10 in Struyf et al (1996)
plot(ma)

```

---

 bannerplot

*Plot Banner (of Hierarchical Clustering)*

---

## Description

Draws a “banner”, i.e. basically a horizontal `barplot` visualizing the (agglomerative or divisive) hierarchical clustering or an other binary dendrogram structure.

## Usage

```

bannerplot(x, w = rev(x$height), fromLeft = TRUE,
           main=NULL, sub=NULL, xlab = "Height", adj = 0,
           col = c(2, 0), border = 0, axes = TRUE, frame.plot = axes,
           rev.xax = !fromLeft, xax.pretty = TRUE,
           labels = NULL, nmax.lab = 35, max.strlen = 5,
           yax.do = axes && length(x$order) <= nmax.lab,
           yaxRight = fromLeft, y.mar = 2.4 + max.strlen/2.5, ...)

```

## Arguments

<code>x</code>	a list with components <code>order</code> , <code>order.lab</code> and <code>height</code> when <code>w</code> , the next argument is not specified.
<code>w</code>	non-negative numeric vector of bar widths.
<code>fromLeft</code>	logical, indicating if the banner is from the left or not.
<code>main, sub</code>	main and sub titles, see <code>title</code> .
<code>xlab</code>	x axis label (with ‘correct’ default e.g. for <code>plot.agnes</code> ).
<code>adj</code>	passed to <code>title(main, sub)</code> for string adjustment.
<code>col</code>	vector of length 2, for two horizontal segments.
<code>border</code>	color for bar border; now defaults to background (no border).
<code>axes</code>	logical indicating if axes (and labels) should be drawn at all.
<code>frame.plot</code>	logical indicating the banner should be framed; mainly used when <code>border = 0</code> (as per default).
<code>rev.xax</code>	logical indicating if the x axis should be reversed (as in <code>plot.diana</code> ).
<code>xax.pretty</code>	logical or integer indicating if <code>pretty()</code> should be used for the x axis. <code>xax.pretty = FALSE</code> is mainly for back compatibility.
<code>labels</code>	labels to use on y-axis; the default is constructed from <code>x</code> .
<code>nmax.lab</code>	integer indicating the number of labels which is considered too large for single-name labelling the banner plot.
<code>max.strlen</code>	positive integer giving the length to which strings are truncated in banner plot labeling.
<code>yax.do</code>	logical indicating if a y axis and banner labels should be drawn.

`yaxRight`      logical indicating if the y axis is on the right or left.  
`y.mar`            positive number specifying the margin width to use when banners are labeled (along a y-axis). The default adapts to the string width and optimally would also depend on the font.  
`...`              graphical parameters (see [par](#)) may also be supplied as arguments to this function.

**Note**

This is mainly a utility called from `plot.agnes`, `plot.diana` and `plot.mona`.

**Author(s)**

Martin Maechler (from original code of Kaufman and Rousseeuw).

**Examples**

```
data(agriculture)
bannerplot(agnes(agriculture), main = "Bannerplot")
```

---

`chorSub`
*Subset of C-horizon of Kola Data*

---

**Description**

This is a small rounded subset of the C-horizon data `chorizon` from package **mvoutlier**.

**Usage**

```
data(chorSub)
```

**Format**

A data frame with 61 observations on 10 variables. The variables contain scaled concentrations of chemical elements.

**Details**

This data set was produced from `chorizon` via these statements:

```
data(chorizon, package = "mvoutlier")
chorSub <- round(100*scale(chorizon[,101:110]))[190:250,]
storage.mode(chorSub) <- "integer"
colnames(chorSub) <- gsub("_.*", "", colnames(chorSub))
```

**Source**

Kola Project (1993-1998)

**See Also**

`chorizon` in package **mvoutlier** and other Kola data in the same package.

**Examples**

```
data(chorSub)
summary(chorSub)
pairs(chorSub, gap= .1)# some outliers
```

clara *Clustering Large Applications*

**Description**

Computes a "clara" object, a list representing a clustering of the data into k clusters.

**Usage**

```
clara(x, k, metric = "euclidean", stand = FALSE, samples = 5,
      sampsize = min(n, 40 + 2 * k), trace = 0, medoids.x = TRUE,
      keep.data = medoids.x, rngR = FALSE)
```

**Arguments**

- x data matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed.
- k integer, the number of clusters. It is required that  $0 < k < n$  where  $n$  is the number of observations (i.e.,  $n = \text{nrow}(x)$ ).
- metric character string specifying the metric to be used for calculating dissimilarities between observations. The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences.
- stand logical, indicating if the measurements in  $x$  are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation.
- samples integer, number of samples to be drawn from the dataset.
- sampsize integer, number of observations in each sample. `sampsize` should be higher than the number of clusters ( $k$ ) and at most the number of observations ( $n = \text{nrow}(x)$ ).
- trace integer indicating a *trace level* for diagnostic output during the algorithm.
- medoids.x logical indicating if the medoids should be returned, identically to some rows of the input data  $x$ . If FALSE, `keep.data` must be false as well, and the medoid indices, i.e., row numbers of the medoids will still be returned (`i.med` component), and the algorithm saves space by needing one copy less of  $x$ .
- keep.data logical indicating if the (*scaled* if `stand` is true) data should be kept in the result.  
Setting this to FALSE saves memory (and hence time), but disables `clusplot()` ing of the result. Use `medoids.x = FALSE` to save even more memory.
- rngR logical indicating if R's random number generator should be used instead of the primitive clara()-builtin one. If true, this also means that each call to `clara()` returns a different result – though only slightly different in good situations.

## Details

`clara` is fully described in chapter 3 of Kaufman and Rousseeuw (1990). Compared to other partitioning methods such as `pam`, it can deal with much larger datasets. Internally, this is achieved by considering sub-datasets of fixed size (`sampsize`) such that the time and storage requirements become linear in  $n$  rather than quadratic.

Each sub-dataset is partitioned into  $k$  clusters using the same algorithm as in `pam`.

Once  $k$  representative objects have been selected from the sub-dataset, each observation of the entire dataset is assigned to the nearest medoid.

The sum of the dissimilarities of the observations to their closest medoid is used as a measure of the quality of the clustering. The sub-dataset for which the sum is minimal, is retained. A further analysis is carried out on the final partition.

Each sub-dataset is forced to contain the medoids obtained from the best sub-dataset until then. Randomly drawn observations are added to this set until `sampsize` has been reached.

## Value

an object of class "clara" representing the clustering. See `clara.object` for details.

## Note

By default, the random sampling is implemented with a *very* simple scheme (with period  $2^{16} = 65536$ ) inside the Fortran code, independently of R's random number generation, and as a matter of fact, deterministically. Alternatively, we recommend setting `rngR = TRUE` which uses R's random number generators. Then, `clara()` results are made reproducible typically by using `set.seed()` before calling `clara`.

The storage requirement of `clara` computation (for small  $k$ ) is about  $O(n \times p) + O(j^2)$  where  $j = \text{sampsize}$ , and  $(n, p) = \text{dim}(x)$ . The CPU computing time (again assuming small  $k$ ) is about  $O(n \times p \times j^2 \times N)$ , where  $N = \text{samples}$ .

For "small" datasets, the function `pam` can be used directly. What can be considered *small*, is really a function of available computing power, both memory (RAM) and speed. Originally (1990), "small" meant less than 100 observations; in 1997, the authors said "*small (say with fewer than 200 observations)*"; as of 2006, you can use `pam` with several thousand observations.

## Author(s)

Kaufman and Rousseeuw (see `agnes`), originally. All arguments from `trace` on, and most R documentation and all tests by Martin Maechler.

## See Also

`agnes` for background and references; `clara.object`, `pam`, `partition.object`, `plot.partition`.

## Examples

```
## generate 500 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(200,0,8), rnorm(200,0,8)),
           cbind(rnorm(300,50,8), rnorm(300,50,8)))
clarax <- clara(x, 2)
clarax
clarax$clusinfo
plot(clarax)
```

```
## `xclara' is an artificial data set with 3 clusters of 1000 bivariate
## objects each.
data(xclara)
(clx3 <- clara(xclara, 3))
## Plot similar to Figure 5 in Struyf et al (1996)
## Not run: plot(clx3, ask = TRUE)

## Try 100 times *different* random samples -- for reliability:
nSim <- 100
nCl <- 3 # = no.classes
set.seed(421) # (reproducibility)
cl <- matrix(NA, nrow(xclara), nSim)
for(i in 1:nSim)
  cl[,i] <- clara(xclara, nCl, medoids.x = FALSE, rngR = TRUE)$cluster
tcl <- apply(cl, 1, tabulate, nbins = nCl)
## those that are not always in same cluster (5 out of 3000 for this seed):
(iDoubt <- which(apply(tcl, 2, function(n) all(n < nSim))))
if(length(iDoubt)) { # (not for all seeds)
  tabD <- tcl[,iDoubt, drop=FALSE]
  dimnames(tabD) <- list(cluster = paste(1:nCl), obs = format(iDoubt))
  t(tabD) # how many times in which clusters
}
```

---

clara.object

*Clustering Large Applications (CLARA) Object*

---

### Description

The objects of class "clara" represent a partitioning of a large dataset into clusters and are typically returned from [clara](#).

### Value

A legitimate clara object is a list with the following components:

sample	labels or case numbers of the observations in the best sample, that is, the sample used by the clara algorithm for the final partition.
medoids	the medoids or representative objects of the clusters. It is a matrix with in each row the coordinates of one medoid. Possibly NULL, namely when the object resulted from clara(*, medoids.x=FALSE). Use the following i.med in that case.
i.med	the <i>indices</i> of the medoids above: medoids <- x[i.med,] where x is the original data matrix in clara(x,*).
clustering	the clustering vector, see <a href="#">partition.object</a> .
objective	the objective function for the final clustering of the entire dataset.
clusinfo	matrix, each row gives numerical information for one cluster. These are the cardinality of the cluster (number of observations), the maximal and average dissimilarity between the observations in the cluster and the cluster's medoid. The last column is the maximal dissimilarity between the observations in the

	cluster and the cluster's medoid, divided by the minimal dissimilarity between the cluster's medoid and the medoid of any other cluster. If this ratio is small, the cluster is well-separated from the other clusters.
diss	dissimilarity (maybe NULL), see <a href="#">partition.object</a> .
silinfo	list with silhouette width information for the best sample, see <a href="#">partition.object</a> .
call	generating call, see <a href="#">partition.object</a> .
data	matrix, possibly standardized, or NULL, see <a href="#">partition.object</a> .

### Methods, Inheritance

The "clara" class has methods for the following generic functions: `print`, `summary`.

The class "clara" inherits from "partition". Therefore, the generic functions `plot` and `clusplot` can be used on a clara object.

### See Also

[clara](#), [dissimilarity.object](#), [partition.object](#), [plot.partition](#).

---

clusplot

*Cluster Plot - Generic Function*

---

### Description

Draws a 2-dimensional "clusplot" on the current graphics device. This is a generic function with a default and `partition` method.

### Usage

```
clusplot(x, ...)
```

### Arguments

<code>x</code>	an R object.
<code>...</code>	additional arguments for <a href="#">methods</a> . Graphical parameters (see <a href="#">par</a> ) may also be supplied as arguments to this function.

### Side Effects

a 2-dimensional clusplot is created on the current graphics device.

### See Also

(for references and examples) [clusplot.default](#), [clusplot.partition](#), [partition.object](#), [pam](#), [fanny](#), [clara](#).

---

clusplot.default     *Bivariate Cluster Plot (clusplot) Default Method*

---

### Description

Creates a bivariate plot visualizing a partition (clustering) of the data. All observation are represented by points in the plot, using principal components or multidimensional scaling. Around each cluster an ellipse is drawn.

### Usage

```
## Default S3 method:
clusplot(x, clus, diss = FALSE, cor = TRUE, stand = FALSE,
         lines = 2, shade = FALSE, color = FALSE,
         labels= 0, plotchar = TRUE,
         col.p = "dark green", col.txt = col.p,
         col.clus = if(color) c(2, 4, 6, 3) else 5,
         span = TRUE, xlim = NULL, ylim = NULL,
         main = paste("CLUSPLOT(", deparse(substitute(x)), ")"),
         sub = paste("These two components explain",
                    round(100 * var.dec, digits = 2), "% of the point variability."),
         verbose = getOption("verbose"),
         ...)
```

### Arguments

<code>x</code>	matrix or data frame, or dissimilarity matrix, depending on the value of the <code>diss</code> argument.  In case of a matrix (alike), each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed. They are replaced by the median of the corresponding variable. When some variables or some observations contain only missing values, the function stops with a warning message.  In case of a dissimilarity matrix, <code>x</code> is the output of <code>daisy</code> or <code>dist</code> or a symmetric matrix. Also, a vector of length $n * (n - 1) / 2$ is allowed (where $n$ is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.
<code>clus</code>	a vector of length $n$ representing a clustering of <code>x</code> . For each observation the vector lists the number or name of the cluster to which it has been assigned. <code>clus</code> is often the clustering component of the output of <code>pam</code> , <code>fanny</code> or <code>clara</code> .
<code>diss</code>	logical indicating if <code>x</code> will be considered as a dissimilarity matrix or a matrix of observations by variables (see <code>x</code> argument above).
<code>cor</code>	logical flag, only used when working with a data matrix ( <code>diss = FALSE</code> ). If TRUE, then the variables are scaled to unit variance.
<code>stand</code>	logical flag: if true, then the representations of the $n$ observations in the 2-dimensional plot are standardized.
<code>lines</code>	integer out of 0, 1, 2, used to obtain an idea of the distances between ellipses. The distance between two ellipses E1 and E2 is measured along the line connecting the centers $m1$ and $m2$ of the two ellipses.

In case E1 and E2 overlap on the line through  $m1$  and  $m2$ , no line is drawn. Otherwise, the result depends on the value of `lines`: If

**lines = 0**, no distance lines will appear on the plot;  
**lines = 1**, the line segment between  $m1$  and  $m2$  is drawn;  
**lines = 2**, a line segment between the boundaries of E1 and E2 is drawn (along the line connecting  $m1$  and  $m2$ ).

shade	logical flag: if TRUE, then the ellipses are shaded in relation to their density. The density is the number of points in the cluster divided by the area of the ellipse.
color	logical flag: if TRUE, then the ellipses are colored with respect to their density. With increasing density, the colors are light blue, light green, red and purple. To see these colors on the graphics device, an appropriate color scheme should be selected (we recommend a white background).
labels	integer code, currently one of 0,1,2,3,4 and 5. If <b>labels= 0</b> , no labels are placed in the plot; <b>labels= 1</b> , points and ellipses can be identified in the plot (see <code>identify</code> ); <b>labels= 2</b> , all points and ellipses are labelled in the plot; <b>labels= 3</b> , only the points are labelled in the plot; <b>labels= 4</b> , only the ellipses are labelled in the plot. <b>labels= 5</b> , the ellipses are labelled in the plot, and points can be identified. The levels of the vector <code>clus</code> are taken as labels for the clusters. The labels of the points are the rownames of <code>x</code> if <code>x</code> is matrix like. Otherwise ( <code>diss = TRUE</code> ), <code>x</code> is a vector, point labels can be attached to <code>x</code> as a "Labels" attribute ( <code>attr(x, "Labels")</code> ), as is done for the output of <code>daisy</code> . A possible <code>names</code> attribute of <code>clus</code> will not be taken into account.
plotchar	logical flag: if TRUE, then the plotting symbols differ for points belonging to different clusters.
span	logical flag: if TRUE, then each cluster is represented by the ellipse with smallest area containing all its points. (This is a special case of the minimum volume ellipsoid.) If FALSE, the ellipse is based on the mean and covariance matrix of the same points. While this is faster to compute, it often yields a much larger ellipse. There are also some special cases: When a cluster consists of only one point, a tiny circle is drawn around it. When the points of a cluster fall on a straight line, <code>span=FALSE</code> draws a narrow ellipse around it and <code>span=TRUE</code> gives the exact line segment.
col.p	color code(s) used for the observation points.
col.txt	color code(s) used for the labels (if <code>labels &gt;= 2</code> ).
col.clus	color code for the ellipses (and their labels); only one if <code>color</code> is false (as per default).
xlim, ylim	numeric vectors of length 2, giving the x- and y- ranges as in <code>plot.default</code> .
main	main title for the plot; by default, one is constructed.
sub	sub title for the plot; by default, one is constructed.
verbose	a logical indicating, if there should be extra diagnostic output; mainly for 'debugging'.
...	Further graphical parameters may also be supplied, see <code>par</code> .

## Details

clusplot uses the functions `princomp` and `cmdscale`. These functions are data reduction techniques. They will represent the data in a bivariate plot. Ellipses are then drawn to indicate the clusters. The further layout of the plot is determined by the optional arguments.

## Value

An invisible list with components:

Distances	When <code>lines</code> is 1 or 2 we obtain a $k$ by $k$ matrix ( $k$ is the number of clusters). The element in $[i, j]$ is the distance between ellipse $i$ and ellipse $j$ . If <code>lines = 0</code> , then the value of this component is NA.
Shading	A vector of length $k$ (where $k$ is the number of clusters), containing the amount of shading per cluster. Let $y$ be a vector where element $i$ is the ratio between the number of points in cluster $i$ and the area of ellipse $i$ . When the cluster $i$ is a line segment, $y[i]$ and the density of the cluster are set to NA. Let $z$ be the sum of all the elements of $y$ without the NAs. Then we put <code>shading = y/z * 37 + 3</code> .

## Side Effects

a visual display of the clustering is plotted on the current graphics device.

## Note

When we have 4 or fewer clusters, then the `color=TRUE` gives every cluster a different color. When there are more than 4 clusters, clusplot uses the function `pam` to cluster the densities into 4 groups such that ellipses with nearly the same density get the same color. `col.clus` specifies the colors used.

The `col.p` and `col.txt` arguments, added for R, are recycled to have length the number of observations. If `col.p` has more than one value, using `color = TRUE` can be confusing because of a mix of point and ellipse colors.

```

---

clusplot.partition *Bivariate Clusplot of a Partitioning Object*

---

**Description**

Clusplot (Clustering Plot) method for an object of class partition.

**Usage**

```
## S3 method for class 'partition':
clusplot(x, main = NULL, dist = NULL, ...)
```

**Arguments**

x                    an object of class "partition", e.g. created by the functions [pam](#), [clara](#), or [fanny](#).

main	title for the plot; when NULL (by default), a title is constructed, using <code>x\$call</code> .
dist	when <code>x</code> does not have a <code>diss</code> nor a data component, e.g., for <code>pam(dist(*), keep.diss=FALSE)</code> , <code>dist</code> must specify the dissimilarity for the clusplot.
...	all optional arguments available for the <code>clusplot.default</code> function (except for the <code>diss</code> one) may also be supplied to this function. Graphical parameters (see <code>par</code> ) may also be supplied as arguments to this function.

## Details

This `clusplot.partition()` method relies on `clusplot.default`.

If the clustering algorithms `pam`, `fanny` and `clara` are applied to a data matrix of observations-by-variables then a clusplot of the resulting clustering can always be drawn. When the data matrix contains missing values and the clustering is performed with `pam` or `fanny`, the dissimilarity matrix will be given as input to `clusplot`. When the clustering algorithm `clara` was applied to a data matrix with NAs then `clusplot` will replace the missing values as described in `clusplot.default`, because a dissimilarity matrix is not available.

## Value

An invisible list with components

Distances	When option <code>lines</code> is 1 or 2 we obtain a <code>k</code> by <code>k</code> matrix ( <code>k</code> is the number of clusters). The element at row <code>j</code> and column <code>s</code> is the distance between ellipse <code>j</code> and ellipse <code>s</code> . If <code>lines=0</code> , then the value of this component is NA.
Shading	A vector of length <code>k</code> (where <code>k</code> is the number of clusters), containing the amount of shading per cluster. Let <code>y</code> be a vector where element <code>i</code> is the ratio between the number of objects in cluster <code>i</code> and the area of ellipse <code>i</code> . When the cluster <code>i</code> is a line segment, <code>y[i]</code> and the density of the cluster are set to NA. Let <code>z</code> be the sum of all the elements of <code>y</code> without the NAs. Then we put <code>shading = y/z * 37 + 3</code> .

## See Also

`clusplot.default` for references; `partition.object`, `pam`, `pam.object`, `clara`, `clara.object`, `fanny`, `fanny.object`, `par`.

## Examples

```
## generate 25 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)),
           cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))
clusplot(pam(x, 2))
## add noise, and try again :
x4 <- cbind(x, rnorm(25), rnorm(25))
clusplot(pam(x4, 2))
```

coef.hclust

*Agglomerative Coefficient for 'hclust' Objects***Description**

Computes the “agglomerative coefficient”, measuring the clustering structure of the dataset.

For each observation  $i$ , denote by  $m(i)$  its dissimilarity to the first cluster it is merged with, divided by the dissimilarity of the merger in the final step of the algorithm. The agglomerative coefficient is the average of all  $1 - m(i)$ . It can also be seen as the average width (or the percentage filled) of the banner plot.

Because it grows with the number of observations, this measure should not be used to compare datasets of very different sizes.

**Usage**

```
coef.hclust(object, ...)
## S3 method for class 'hclust':
coef(object, ...)
## S3 method for class 'twins':
coef(object, ...)
```

**Arguments**

object	an object of class "hclust" or "twins", i.e., typically the result of <code>hclust(.)</code> , <code>agnes(.)</code> , or <code>diana(.)</code> . Since <code>coef.hclust</code> only uses <code>object\$heights</code> , and <code>object\$merge</code> , <code>object</code> can be any list-like object with appropriate <code>merge</code> and <code>heights</code> components.
...	currently unused potential further arguments

**Value**

a number specifying the *agglomerative* (or *divisive* for `diana` objects) coefficient as defined by Kaufman and Rousseeuw, see `agnes.object` \$ `ac` or `diana.object` \$ `dc`.

**Examples**

```
data(agriculture)
aa <- agnes(agriculture)
coef(aa) # really just extracts aa$ac
coef(as.hclust(aa)) # recomputes
```

daisy

*Dissimilarity Matrix Calculation***Description**

Compute all the pairwise dissimilarities (distances) between observations in the data set. The original variables may be of mixed types.

**Usage**

```
daisy(x, metric = c("euclidean", "manhattan", "gower"),
      stand = FALSE, type = list())
```

**Arguments**

- |                     |   |
|---------------------|---|
| <code>x</code>      | numeric matrix or data frame. Dissimilarities will be computed between the rows of <code>x</code> . Columns of mode <code>numeric</code> (i.e. all columns when <code>x</code> is a matrix) will be recognized as interval scaled variables, columns of class <code>factor</code> will be recognized as nominal variables, and columns of class <code>ordered</code> will be recognized as ordinal variables. Other variable types should be specified with the <code>type</code> argument. Missing values (NAs) are allowed.   |
| <code>metric</code> | character string specifying the metric to be used. The currently available options are "euclidean" (the default), "manhattan" and "gower". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences.<br><br>"Gower's distance" is chosen by metric "gower" or automatically if some columns of <code>x</code> are not numeric. Also known as Gower's coefficient (1971), expressed as a dissimilarity, this implies that a particular standardisation will be applied to each variable, and the "distance" between two units is the sum of all the variable-specific distances, see the details section. |
| <code>stand</code>  | logical flag: if TRUE, then the measurements in <code>x</code> are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation.<br><br>If not all columns of <code>x</code> are numeric, <code>stand</code> will be ignored and Gower's standardization (based on the <a href="#">range</a> ) will be applied in any case, see argument <code>metric</code> , above, and the details section.  |
| <code>type</code>   | list for specifying some (or all) of the types of the variables (columns) in <code>x</code> . The list may contain the following components: "ordratio" (ratio scaled variables to be treated as ordinal variables), "logratio" (ratio scaled variables that must be logarithmically transformed), "asymm" (asymmetric binary) and "symm" (symmetric binary variables). Each component's value is a vector, containing the names or the numbers of the corresponding columns of <code>x</code> . Variables not mentioned in the <code>type</code> list are interpreted as usual (see argument <code>x</code> ).   |

**Details**

`daisy` is fully described in chapter 1 of Kaufman and Rousseeuw (1990). Compared to `dist` whose input must be numeric variables, the main feature of `daisy` is its ability to handle other

variable types as well (e.g. nominal, ordinal, (a)symmetric binary) even when different types occur in the same data set.

The handling of nominal, ordinal, and (a)symmetric binary data is achieved by using the general dissimilarity coefficient of Gower (1971). If `x` contains any columns of these data-types, both arguments `metric` and `stand` will be ignored and Gower's coefficient will be used as the metric. This can also be activated for purely numeric data by `metric = "gower"`. With that, each variable (column) is first standardized by dividing each entry by the range of the corresponding variable.

Note that setting the type to `symm` (symmetric binary) gives the same dissimilarities as using `nominal` (which is chosen for non-ordered factors) only when no missing values are present, and more efficiently.

Note that `daisy` now gives a warning when 2-valued numerical variables don't have an explicit `type` specified, because the reference authors recommend to consider using `asymm`.

In the `daisy` algorithm, missing values in a row of `x` are not included in the dissimilarities involving that row. There are two main cases,

1. If all variables are interval scaled, the metric is "euclidean", and `ng` is the number of columns in which neither row `i` and `j` have NAs, then the dissimilarity `d(i,j)` returned is  $\sqrt{\text{ncol}(x)/ng}$  times the Euclidean distance between the two vectors of length `ng` shortened to exclude NAs. The rule is similar for the "manhattan" metric, except that the coefficient is  $\text{ncol}(x)/ng$ . If `ng` is zero, the dissimilarity is NA.

2. When some variables have a type other than interval scaled, the dissimilarity between two rows is the weighted sum of the contributions of each variable.

The weight becomes zero when that variable is missing in either or both rows, or when the variable is asymmetric binary and both values are zero. In all other situations, the weight of the variable is 1.

The contribution of a nominal or binary variable to the total dissimilarity is 0 if both values are equal, 1 otherwise. The contribution of other variables is the absolute difference of both values, divided by the total range of that variable. Ordinal variables are first converted to ranks.

If `nok` is the number of nonzero weights, the dissimilarity is multiplied by the factor  $1/nok$  and thus ranges between 0 and 1. If `nok = 0`, the dissimilarity is set to NA.

## Value

an object of class "dissimilarity" containing the dissimilarities among the rows of `x`. This is typically the input for the functions `pam`, `fanny`, `agnes` or `diana`. For more details, see [dissimilarity.object](#).

## Background

Dissimilarities are used as inputs to cluster analysis and multidimensional scaling. The choice of metric may have a large impact.

---

diana

*Divisive ANAlysis Clustering*

---

**Description**

Computes a divisive hierarchical clustering of the dataset returning an object of class `diana`.

**Usage**

```
diana(x, diss = inherits(x, "dist"), metric = "euclidean", stand = FALSE,
  keep.diss = n < 100, keep.data = !diss)
```

**Arguments**

<code>x</code>	<p>data matrix or data frame, or dissimilarity matrix or object, depending on the value of the <code>diss</code> argument.</p> <p>In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) <i>are</i> allowed.</p> <p>In case of a dissimilarity matrix, <code>x</code> is typically the output of <a href="#">daisy</a> or <a href="#">dist</a>. Also a vector of length <math>n*(n-1)/2</math> is allowed (where <math>n</math> is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are <i>not</i> allowed.</p>
<code>diss</code>	<p>logical flag: if TRUE (default for <code>dist</code> or <code>dissimilarity</code> objects), then <code>x</code> will be considered as a dissimilarity matrix. If FALSE, then <code>x</code> will be considered as a matrix of observations by variables.</p>

<code>metric</code>	character string specifying the metric to be used for calculating dissimilarities between observations. The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored.
<code>stand</code>	logical; if true, the measurements in <code>x</code> are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation. If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored.
<code>keep.diss, keep.data</code>	logicals indicating if the dissimilarities and/or input data <code>x</code> should be kept in the result. Setting these to <code>FALSE</code> can give much smaller results and hence even save memory allocation <i>time</i> .

### Details

`diana` is fully described in chapter 6 of Kaufman and Rousseeuw (1990). It is probably unique in computing a divisive hierarchy, whereas most other software for hierarchical clustering is agglomerative. Moreover, `diana` provides (a) the divisive coefficient (see `diana.object`) which measures the amount of clustering structure found; and (b) the banner, a novel graphical display (see `plot.diana`).

The `diana`-algorithm constructs a hierarchy of clusterings, starting with one large cluster containing all  $n$  observations. Clusters are divided until each cluster contains only a single observation.

At each stage, the cluster with the largest diameter is selected. (The diameter of a cluster is the largest dissimilarity between any two of its observations.)

To divide the selected cluster, the algorithm first looks for its most disparate observation (i.e., which has the largest average dissimilarity to the other observations of the selected cluster). This observation initiates the "splinter group". In subsequent steps, the algorithm reassigns observations that are closer to the "splinter group" than to the "old party". The result is a division of the selected cluster into two new clusters.

### Value

an object of class "diana" representing the clustering; this class has methods for the following generic functions: `print`, `summary`, `plot`.

Further, the class "diana" inherits from "twins". Therefore, the generic function `pltree` can be used on a `diana` object, and an `as.hclust` method is available.

A legitimate `diana` object is a list with the following components:

<code>order</code>	a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.
<code>order.lab</code>	a vector similar to <code>order</code> , but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled.
<code>height</code>	a vector with the diameters of the clusters prior to splitting.
<code>dc</code>	the divisive coefficient, measuring the clustering structure of the dataset. For each observation $i$ , denote by $d(i)$ the diameter of the last cluster to which it belongs (before being split off as a single observation), divided by the diameter of the whole dataset. The <code>dc</code> is the average of all $1 - d(i)$ . It can also be

	seen as the average width (or the percentage filled) of the banner plot. Because <code>dc</code> grows with the number of observations, this measure should not be used to compare datasets of very different sizes.
<code>merge</code>	an (n-1) by 2 matrix, where n is the number of observations. Row <i>i</i> of <code>merge</code> describes the split at step n-i of the clustering. If a number <i>j</i> in row <i>r</i> is negative, then the single observation $ j $ is split off at stage n-r. If <i>j</i> is positive, then the cluster that will be splitted at stage n-j (described by row <i>j</i> ), is split off at stage n-r.
<code>diss</code>	an object of class "dissimilarity", representing the total dissimilarity matrix of the dataset.
<code>data</code>	a matrix containing the original or standardized measurements, depending on the <code>stand</code> option of the function <code>agnes</code> . If a dissimilarity matrix was given as input structure, then this component is not available.

**See Also**

`agnes` also for background and references; `cutree` (and `as.hclust`) for grouping extraction; `daisy`, `dist`, `plot.diana`, `twins.object`.

**Examples**

```
data(votes.repub)
dv <- diana(votes.repub, metric = "manhattan", stand = TRUE)
print(dv)
plot(dv)

## Cut into 2 groups:
dv2 <- cutree(as.hclust(dv), k = 2)
table(dv2) # 8 and 42 group members
rownames(votes.repub)[dv2 == 1]

## For two groups, does the metric matter ?
dv0 <- diana(votes.repub, stand = TRUE) # default: Euclidean
dv.2 <- cutree(as.hclust(dv0), k = 2)
table(dv2 == dv.2) ## identical group assignments

data(agriculture)
## Plot similar to Figure 8 in ref
## Not run: plot(diana(agriculture), ask = TRUE)
```

---

dissimilarity.object

*Dissimilarity Matrix Object*

---

**Description**

Objects of class "dissimilarity" representing the dissimilarity matrix of a dataset.

**Value**

The dissimilarity matrix is symmetric, and hence its lower triangle (column wise) is represented as a vector to save storage space. If the object, is called `do`, and `n` the number of observations, i.e., `n <- attr(do, "Size")`, then for  $i < j \leq n$ , the dissimilarity between (row)  $i$  and  $j$  is `do[n*(i-1) - i*(i-1)/2 + j-i]`. The length of the vector is  $n*(n-1)/2$ , i.e., of order  $n^2$ .

"dissimilarity" objects also inherit from class `dist` and can use `dist` methods, in particular, `as.matrix`, such that  $d_{ij}$  from above is just `as.matrix(do)[i, j]`.

The object has the following attributes:

Size	the number of observations in the dataset.
Metric	the metric used for calculating the dissimilarities. Possible values are "euclidean", "manhattan", "mixed" (if variables of different types were present in the dataset), and "unspecified".
Labels	optionally, contains the labels, if any, of the observations of the dataset.
NA.message	optionally, if a dissimilarity could not be computed, because of too many missing values for some observations of the dataset.
Types	when a mixed metric was used, the types for each variable as one-letter codes (as in the book, e.g. p.54): <ul style="list-style-type: none"> <li><b>A</b> Asymmetric binary</li> <li><b>S</b> Symmetric binary</li> <li><b>N</b> Nominal (factor)</li> <li><b>O</b> Ordinal (ordered factor)</li> <li><b>I</b> Interval scaled (numeric)</li> <li><b>T</b> raTio to be log transformed (positive numeric)</li> </ul>
	.

**GENERATION**

`daisy` returns this class of objects. Also the functions `pam`, `clara`, `fanny`, `agnes`, and `diana` return a `dissimilarity` object, as one component of their return objects.

**METHODS**

The "dissimilarity" class has methods for the following generic functions: `print`, `summary`.

**See Also**

`daisy`, `dist`, `pam`, `clara`, `fanny`, `agnes`, `diana`.

ellipsoidhull

Compute the Ellipsoid Hull or Spanning Ellipsoid of a Point Set

**Description**

Compute the “ellipsoid hull” or “spanning ellipsoid”, i.e. the ellipsoid of minimal volume (‘area’ in 2D) such that all given points lie just inside or on the boundary of the ellipsoid.

**Usage**

```
ellipsoidhull(x, tol=0.01, maxit=5000,
             ret.wt = FALSE, ret.sqdist = FALSE, ret.pr = FALSE)
## S3 method for class 'ellipsoid':
print(x, digits = max(1, getOption("digits") - 2), ...)
```

**Arguments**

`x` the  $n$   $p$ -dimensional points as numeric  $n \times p$  matrix.

`tol` convergence tolerance for Titterington’s algorithm. Setting this to much smaller values may drastically increase the number of iterations needed, and you may want to increase `maxit` as well.

`maxit` integer giving the maximal number of iteration steps for the algorithm.

`ret.wt`, `ret.sqdist`, `ret.pr` logicals indicating if additional information should be returned, `ret.wt` specifying the *weights*, `ret.sqdist` the *squared distances* and `ret.pr` the final **probabilities** in the algorithms.

`digits, ...` the usual arguments to `print` methods.

**Details**

The “spanning ellipsoid” algorithm is said to stem from Titterington(1976), in Pison et al(1999) who use it for `clusplot.default`.

The problem can be seen as a special case of the “Min.Vol.” ellipsoid of which a more flexible and general implementation is `cov.mve` in the MASS package.

**Value**

an object of class "ellipsoid", basically a `list` with several components, comprising at least

`cov`  $p \times p$  covariance matrix description the ellipsoid.

`loc`  $p$ -dimensional location of the ellipsoid center.

`d2` average squared radius. Further,  $d2 = t^2$ , where  $t$  is “the value of a t-statistic on the ellipse boundary” (from `ellipse` in the **ellipse** package), and hence, more usefully,  $d2 = qchisq(alpha, df = p)$ , where `alpha` is the confidence level for  $p$ -variate normally distributed data with location and covariance `loc` and `cov` to lie inside the ellipsoid.

`wt` the vector of weights iff `ret.wt` was true.

`sqdist` the vector of squared distances iff `ret.sqdist` was true.

`prob` the vector of algorithm probabilities iff `ret.pr` was true.

<code>it</code>	number of iterations used.
<code>tol, maxit</code>	just the input argument, see above.
<code>eps</code>	the achieved tolerance which is the maximal squared radius minus $p$ .
<code>ierr</code>	error code as from the algorithm; 0 means <i>ok</i> .
<code>conv</code>	logical indicating if the converged. This is defined as <code>it &lt; maxit &amp;&amp; ierr == 0</code> .

### Author(s)

Martin Maechler did the present class implementation; Rousseeuw et al did the underlying code.

`predict.ellipsoid` which is also the `predict` method for `ellipsoid` objects. `volume.ellipsoid` for an example of ‘manual’ `ellipsoid` object construction; further `ellipse` from package **ellipse** and `ellipsePoints` from package **sfsmisc**. `chull` for the convex hull, `clusplot` which makes use of this; `cov.mve`.

### Examples

```
x <- rnorm(100)
xy <- unname(cbind(x, rnorm(100) + 2*x + 10))
exy <- ellipsoidhull(xy)
exy # >> calling print.ellipsoid()

plot(xy)
lines(predict(exy))
points(rbind(exy$loc), col = "red", cex = 3, pch = 13)

exy <- ellipsoidhull(xy, tol = 1e-7, ret.wt = TRUE, ret.sq = TRUE)
str(exy) # had small `tol`, hence many iterations
(ii <- which(zapsmall(exy $ wt) > 1e-6)) # only about 4 to 6 points
round(exy$wt[ii], 3); sum(exy$wt[ii]) # sum to 1
```

### Description

Computes a fuzzy clustering of the data into  $k$  clusters.

**Usage**

```
fanny(x, k, diss = inherits(x, "dist"), memb.exp = 2,
      metric = c("euclidean", "manhattan", "SqEuclidean"),
      stand = FALSE, iniMem.p = NULL, cluster.only = FALSE,
      keep.diss = !diss && !cluster.only && n < 100,
      keep.data = !diss && !cluster.only,
      maxit = 500, tol = 1e-15, trace.lev = 0)
```

**Arguments**

- |                      |  |
|----------------------|--|
| x                    | data matrix or data frame, or dissimilarity matrix, depending on the value of the <code>diss</code> argument.<br><br>In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed.<br><br>In case of a dissimilarity matrix, x is typically the output of <code>daisy</code> or <code>dist</code> . Also a vector of length $n*(n-1)/2$ is allowed (where n is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed. |
| k                    | integer giving the desired number of clusters. It is required that $0 < k < n/2$ where n is the number of observations.  |
| diss                 | logical flag: if TRUE (default for <code>dist</code> or <code>dissimilarity</code> objects), then x is assumed to be a dissimilarity matrix. If FALSE, then x is treated as a matrix of observations by variables.   |
| memb.exp             | number r strictly larger than 1 specifying the <i>membership exponent</i> used in the fit criterion; see the ‘Details’ below. Default: 2 which used to be hardwired inside FANNY.  |
| metric               | character string specifying the metric to be used for calculating dissimilarities between observations. Options are "euclidean" (default), "manhattan", and "SqEuclidean". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences, and "SqEuclidean", the <i>squared</i> euclidean distances are sum-of-squares of differences. Using this last option is equivalent (but somewhat slower) to computing so called “fuzzy C-means”.<br>If x is already a dissimilarity matrix, then this argument will be ignored.   |
| stand                | logical; if true, the measurements in x are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable’s mean value and dividing by the variable’s mean absolute deviation. If x is already a dissimilarity matrix, then this argument will be ignored.  |
| iniMem.p             | numeric $n \times k$ matrix or NULL (by default); can be used to specify a starting membership matrix, i.e., a matrix of non-negative numbers, each row summing to one.  |
| cluster.only         | logical; if true, no silhouette information will be computed and returned, see details.  |
| keep.diss, keep.data | logicals indicating if the dissimilarities and/or input data x should be kept in the result. Setting these to FALSE can give smaller results and hence also save memory allocation <i>time</i> .   |

<code>maxit, tol</code>	maximal number of iterations and default tolerance for convergence (relative convergence of the fit criterion) for the FANNY algorithm. The defaults <code>maxit = 500</code> and <code>tol = 1e-15</code> used to be hardwired inside the algorithm.
<code>trace.lev</code>	integer specifying a trace level for printing diagnostics during the C-internal algorithm. Default 0 does not print anything; higher values print increasingly more.

## Details

In a fuzzy clustering, each observation is “spread out” over the various clusters. Denote by  $u_{iv}$  the membership of observation  $i$  to cluster  $v$ .

The memberships are nonnegative, and for a fixed observation  $i$  they sum to 1. The particular method `fanny` stems from chapter 4 of Kaufman and Rousseeuw (1990) (see the references in `daisy`) and has been extended by Martin Maechler to allow user specified `memb.exp`, `iniMem.p`, `maxit`, `tol`, etc.

Fanny aims to minimize the objective function

$$\sum_{v=1}^k \frac{\sum_{i=1}^n \sum_{j=1}^n u_{iv}^r u_{jv}^r d(i, j)}{2 \sum_{j=1}^n u_{jv}^r}$$

where  $n$  is the number of observations,  $k$  is the number of clusters,  $r$  is the membership exponent `memb.exp` and  $d(i, j)$  is the dissimilarity between observations  $i$  and  $j$ .

Note that  $r \rightarrow 1$  gives increasingly crisper clusterings whereas  $r \rightarrow \infty$  leads to complete fuzziness. Kaufman & Rousseeuw (1990), p.191 note that values too close to 1 can lead to slow convergence. Further note that even the default,  $r = 2$  can lead to complete fuzziness, i.e., memberships  $u_{iv} \equiv 1/k$ . In that case a warning is signalled and the user is advised to choose a smaller `memb.exp (= r)`.

Compared to other fuzzy clustering methods, `fanny` has the following features: (a) it also accepts a dissimilarity matrix; (b) it is more robust to the spherical cluster assumption; (c) it provides a novel graphical display, the silhouette plot (see `plot.partition`).

## Value

an object of class "fanny" representing the clustering. See `fanny.object` for details.

## See Also

`agnes` for background and references; `fanny.object`, `partition.object`, `plot.partition`, `daisy`, `dist`.

## Examples

```
## generate 10+15 objects in two clusters, plus 3 objects lying
## between those clusters.
x <- rbind(cbind(rnorm(10, 0, 0.5), rnorm(10, 0, 0.5)),
           cbind(rnorm(15, 5, 0.5), rnorm(15, 5, 0.5)),
           cbind(rnorm( 3, 3.2, 0.5), rnorm( 3, 3.2, 0.5)))
fannyx <- fanny(x, 2)
## Note that observations 26:28 are "fuzzy" (closer to # 2):
fannyx
summary(fannyx)
plot(fannyx)

(fan.x.15 <- fanny(x, 2, memb.exp = 1.5)) # 'crispier' for obs. 26:28
```

```
(fanny(x, 2, memb.exp = 3))           # more fuzzy in general

data(ruspini)
f4 <- fanny(ruspini, 4)
stopifnot(rle(f4$clustering)$lengths == c(20,23,17,15))
plot(f4, which = 1)
## Plot similar to Figure 6 in Stryuf et al (1996)
plot(fanny(ruspini, 5))
```

fanny.object

*Fuzzy Analysis (FANNY) Object***Description**

The objects of class "fanny" represent a fuzzy clustering of a dataset.

**Value**

A legitimate fanny object is a list with the following components:

membership	matrix containing the memberships for each pair consisting of an observation and a cluster.
memb.exp	the membership exponent used in the fitting criterion.
coeff	Dunn's partition coefficient $F(k)$ of the clustering, where $k$ is the number of clusters. $F(k)$ is the sum of all <i>squared</i> membership coefficients, divided by the number of observations. Its value is between $1/k$ and 1. The normalized form of the coefficient is also given. It is defined as $(F(k) - 1/k)/(1 - 1/k)$ , and ranges between 0 and 1. A low value of Dunn's coefficient indicates a very fuzzy clustering, whereas a value close to 1 indicates a near-crisp clustering.
clustering	the clustering vector of the nearest crisp clustering, see <a href="#">partition.object</a> .
k.crisp	integer ( $\leq k$ ) giving the number of <i>crisp</i> clusters; can be less than $k$ , where it's recommended to decrease <code>memb.exp</code> .
objective	named vector containing the minimal value of the objective function reached by the FANNY algorithm and the relative convergence tolerance <code>tol</code> used.
convergence	named vector with <code>iterations</code> , the number of iterations needed and <code>converged</code> indicating if the algorithm converged (in <code>maxit</code> iterations within convergence tolerance <code>tol</code> ).
diss	an object of class "dissimilarity", see <a href="#">partition.object</a> .
call	generating call, see <a href="#">partition.object</a> .
silinfo	list with silhouette information of the nearest crisp clustering, see <a href="#">partition.object</a> .
data	matrix, possibly standardized, or NULL, see <a href="#">partition.object</a> .

**GENERATION**

These objects are returned from [fanny](#).

**METHODS**

The "fanny" class has methods for the following generic functions: `print`, `summary`.

**INHERITANCE**

The class "fanny" inherits from "partition". Therefore, the generic functions `plot` and `clusplot` can be used on a fanny object.

**See Also**

`fanny`, `print.fanny`, `dissimilarity.object`, `partition.object`,  
`plot.partition`.

---

flower

*Flower Characteristics*

---

**Description**

8 characteristics for 18 popular flowers.

**Usage**

```
data(flower)
```

**Format**

A data frame with 18 observations on 8 variables:

[ , "V1"]	factor	winters
[ , "V2"]	factor	shadow
[ , "V3"]	factor	tubers
[ , "V4"]	factor	color
[ , "V5"]	ordered	soil
[ , "V6"]	ordered	preference
[ , "V7"]	numeric	height
[ , "V8"]	numeric	distance

**V1** winters, is binary and indicates whether the plant may be left in the garden when it freezes.

**V2** shadow, is binary and shows whether the plant needs to stand in the shadow.

**V3** tubers, is asymmetric binary and distinguishes between plants with tubers and plants that grow in any other way.

**V4** color, is nominal and specifies the flower's color (1 = white, 2 = yellow, 3 = pink, 4 = red, 5 = blue).

**V5** soil, is ordinal and indicates whether the plant grows in dry (1), normal (2), or wet (3) soil.

**V6** preference, is ordinal and gives someone's preference ranking going from 1 to 18.

**V7** height, is interval scaled, the plant's height in centimeters.

**V8** distance, is interval scaled, the distance in centimeters that should be left between the plants.

**Source**

The reference below.

## Example 2 in ref
daisy(flower, type = list(asymm = 3))
daisy(flower, type = list(asymm = c(1, 3), ordratio = 7))
```

---

lower.to.upper.tri.inds

*Permute Indices for Triangular Matrices*

---

**Description**

Compute index vectors for extracting or reordering of lower or upper triangular matrices that are stored as contiguous vectors.

**Usage**

```
lower.to.upper.tri.inds(n)
upper.to.lower.tri.inds(n)
```

**Arguments**

n                    integer larger than 1.

**Value**

integer vector containing a permutation of  $1:N$  where  $N = n(n-1)/2$ .

**Note**

these functions are mainly for internal use in the cluster package, and may not remain available (unless we see a good reason).

**See Also**

[upper.tri](#), [lower.tri](#) with a related purpose.

**Examples**

```

m5 <- matrix(NA, 5, 5)
m <- m5; m[lower.tri(m)] <- upper.to.lower.tri.inds(5); m
m <- m5; m[upper.tri(m)] <- lower.to.upper.tri.inds(5); m

stopifnot(lower.to.upper.tri.inds(2) == 1,
          lower.to.upper.tri.inds(3) == 1:3,
          upper.to.lower.tri.inds(3) == 1:3,
          sort(upper.to.lower.tri.inds(5)) == 1:10,
          sort(lower.to.upper.tri.inds(6)) == 1:15)

```

mona

*MONothetic Analysis Clustering of Binary Variables***Description**

Returns a list representing a divisive hierarchical clustering of a dataset with binary variables only.

**Usage**

```
mona(x)
```

**Arguments**

**x** data matrix or data frame in which each row corresponds to an observation, and each column corresponds to a variable. All variables must be binary. A limited number of missing values (NAs) is allowed. Every observation must have at least one value different from NA. No variable should have half of its values missing. There must be at least one variable which has no missing values. A variable with all its non-missing values identical, is not allowed.

**Details**

`mona` is fully described in chapter 7 of Kaufman and Rousseeuw (1990). It is "monothetic" in the sense that each division is based on a single (well-chosen) variable, whereas most other hierarchical methods (including `agnes` and `diana`) are "polythetic", i.e. they use all variables together.

The `mona`-algorithm constructs a hierarchy of clusterings, starting with one large cluster. Clusters are divided until all observations in the same cluster have identical values for all variables.

At each stage, all clusters are divided according to the values of one variable. A cluster is divided into one cluster with all observations having value 1 for that variable, and another cluster with all observations having value 0 for that variable.

The variable used for splitting a cluster is the variable with the maximal total association to the other variables, according to the observations in the cluster to be splitted. The association between variables  $f$  and  $g$  is given by  $a(f,g)*d(f,g) - b(f,g)*c(f,g)$ , where  $a(f,g)$ ,  $b(f,g)$ ,  $c(f,g)$ , and  $d(f,g)$  are the numbers in the contingency table of  $f$  and  $g$ . [That is,  $a(f,g)$  (resp.  $d(f,g)$ ) is the number of observations for which  $f$  and  $g$  both have value 0 (resp. value 1);  $b(f,g)$  (resp.  $c(f,g)$ ) is the number of observations for which  $f$  has value 0 (resp. 1) and  $g$  has value 1 (resp. 0).] The total association of a variable  $f$  is the sum of its associations to all variables.

This algorithm does not work with missing values, therefore the data are revised, e.g. all missing values are filled in. To do this, the same measure of association between variables is used as in the algorithm. When variable  $f$  has missing values, the variable  $g$  with the largest absolute association

to `f` is looked up. When the association between `f` and `g` is positive, any missing value of `f` is replaced by the value of `g` for the same observation. If the association between `f` and `g` is negative, then any missing value of `f` is replaced by the value of `1-g` for the same observation.

### Value

an object of class "mona" representing the clustering. See `mona.object` for details.

### See Also

`agnes` for background and references; `mona.object`, `plot.mona`.

### Examples

```
data(animals)
ma <- mona(animals)
ma
## Plot similar to Figure 10 in Struyf et al (1996)
plot(ma)
```

---

`mona.object`

*Monothetic Analysis (MONA) Object*

---

### Description

The objects of class "mona" represent the divisive hierarchical clustering of a dataset with only binary variables (measurements). This class of objects is returned from `mona`.

### Value

A legitimate `mona` object is a list with the following components:

<code>data</code>	matrix with the same dimensions as the original data matrix, but with factors coded as 0 and 1, and all missing values replaced.
<code>order</code>	a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.
<code>order.lab</code>	a vector similar to <code>order</code> , but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled.
<code>variable</code>	vector of length <code>n-1</code> where <code>n</code> is the number of observations, specifying the variables used to separate the observations of <code>order</code> .
<code>step</code>	vector of length <code>n-1</code> where <code>n</code> is the number of observations, specifying the separation steps at which the observations of <code>order</code> are separated.

### METHODS

The "mona" class has methods for the following generic functions: `print`, `summary`, `plot`.

### See Also

`mona` for examples etc, `plot.mona`.

pam

*Partitioning Around Medoids***Description**

Partitioning (clustering) of the data into  $k$  clusters “around medoids”, a more robust version of K-means.

**Usage**

```
pam(x, k, diss = inherits(x, "dist"), metric = "euclidean",
    medoids = NULL, stand = FALSE, cluster.only = FALSE,
    do.swap = TRUE,
    keep.diss = !diss && !cluster.only && n < 100,
    keep.data = !diss && !cluster.only, trace.lev = 0)
```

**Arguments**

- |              |  |
|--------------|--|
| x            | data matrix or data frame, or dissimilarity matrix or object, depending on the value of the <code>diss</code> argument.<br><br>In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed—as long as every pair of observations has at least one case not missing.<br><br>In case of a dissimilarity matrix, <code>x</code> is typically the output of <code>daisy</code> or <code>dist</code> . Also a vector of length $n*(n-1)/2$ is allowed (where $n$ is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are <i>not</i> allowed. |
| k            | positive integer specifying the number of clusters, less than the number of observations.  |
| diss         | logical flag: if TRUE (default for <code>dist</code> or <code>dissimilarity</code> objects), then <code>x</code> will be considered as a dissimilarity matrix. If FALSE, then <code>x</code> will be considered as a matrix of observations by variables.  |
| metric       | character string specifying the metric to be used for calculating dissimilarities between observations.<br><br>The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored.  |
| medoids      | NULL (default) or length- $k$ vector of integer indices (in $1:n$ ) specifying initial medoids instead of using the ‘ <i>build</i> ’ algorithm.  |
| stand        | logical; if true, the measurements in <code>x</code> are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable’s mean value and dividing by the variable’s mean absolute deviation. If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored.  |
| cluster.only | logical; if true, only the clustering will be computed and returned, see details.  |

<code>do.swap</code>	logical indicating if the <b>swap</b> phase should happen. The default, <code>TRUE</code> , correspond to the original algorithm. On the other hand, the <b>swap</b> phase is much more computer intensive than the <b>build</b> one for large $n$ , so can be skipped by <code>do.swap = FALSE</code> .
<code>keep.diss, keep.data</code>	logicals indicating if the dissimilarities and/or input data $x$ should be kept in the result. Setting these to <code>FALSE</code> can give much smaller results and hence even save memory allocation <i>time</i> .
<code>trace.lev</code>	integer specifying a trace level for printing diagnostics during the build and swap phase of the algorithm. Default 0 does not print anything; higher values print increasingly more.

### Details

`pam` is fully described in chapter 2 of Kaufman and Rousseeuw (1990). Compared to the `k-means` approach in `kmeans`, the function `pam` has the following features: (a) it also accepts a dissimilarity matrix; (b) it is more robust because it minimizes a sum of dissimilarities instead of a sum of squared euclidean distances; (c) it provides a novel graphical display, the silhouette plot (see `plot.partition`) (d) it allows to select the number of clusters using `mean(silhouette(pr))` on the result `pr <- pam(..)`, or directly its component `pr$silinfo$avg.width`, see also [pam.object](#).

When `cluster.only` is true, the result is simply a (possibly named) integer vector specifying the clustering, i.e.,

`pam(x, k, cluster.only=TRUE)` is the same as  
`pam(x, k)$clustering` but computed more efficiently.

The `pam`-algorithm is based on the search for  $k$  representative objects or medoids among the observations of the dataset. These observations should represent the structure of the data. After finding a set of  $k$  medoids,  $k$  clusters are constructed by assigning each observation to the nearest medoid. The goal is to find  $k$  representative objects which minimize the sum of the dissimilarities of the observations to their closest representative object.

By default, when `medoids` are not specified, the algorithm first looks for a good initial set of medoids (this is called the **build** phase). Then it finds a local minimum for the objective function, that is, a solution such that there is no single switch of an observation with a medoid that will decrease the objective (this is called the **swap** phase).

When the `medoids` are specified, their order does *not* matter; in general, the algorithms have been designed to not depend on the order of the observations.

### Value

an object of class "pam" representing the clustering. See [?pam.object](#) for details.

### Note

For large datasets, `pam` may need too much memory or too much computation time since both are  $O(n^2)$ . Then, `clara()` is preferable, see its documentation.

### See Also

[agnes](#) for background and references; [pam.object](#), [clara](#), [daisy](#), [partition.object](#), [plot.partition](#), [dist](#).

**Examples**

```
## generate 25 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)),
           cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))
pamx <- pam(x, 2)
pamx
summary(pamx)
plot(pamx)
## use obs. 1 & 16 as starting medoids -- same result (typically)
(p2m <- pam(x, 2, medoids = c(1,16)))

p3m <- pam(x, 3, trace = 2)
## rather stupid initial medoids:
(p3m. <- pam(x, 3, medoids = 3:1, trace = 1))

pam(daisy(x, metric = "manhattan"), 2, diss = TRUE)

data(ruspini)
## Plot similar to Figure 4 in Stryuf et al (1996)
## Not run: plot(pam(ruspini, 4), ask = TRUE)
```

pam.object

*Partitioning Around Medoids (PAM) Object***Description**

The objects of class "pam" represent a partitioning of a dataset into clusters.

**Value**

A legitimate pam object is a list with the following components:

medoids	the medoids or representative objects of the clusters. If a dissimilarity matrix was given as input to pam, then a vector of numbers or labels of observations is given, else medoids is a matrix with in each row the coordinates of one medoid.
id.med	integer vector of <i>indices</i> giving the medoid observation numbers.
clustering	the clustering vector, see <a href="#">partition.object</a> .
objective	the objective function after the first and second step of the pam algorithm.
isolation	vector with length equal to the number of clusters, specifying which clusters are isolated clusters (L- or L*-clusters) and which clusters are not isolated. A cluster is an L*-cluster iff its diameter is smaller than its separation. A cluster is an L-cluster iff for each observation <i>i</i> the maximal dissimilarity between <i>i</i> and any other observation of the cluster is smaller than the minimal dissimilarity between <i>i</i> and any observation of another cluster. Clearly each L*-cluster is also an L-cluster.
clusinfo	matrix, each row gives numerical information for one cluster. These are the cardinality of the cluster (number of observations), the maximal and average dissimilarity between the observations in the cluster and the cluster's medoid,

the diameter of the cluster (maximal dissimilarity between two observations of the cluster), and the separation of the cluster (minimal dissimilarity between an observation of the cluster and an observation of another cluster).

silinfo list with silhouette width information, see [partition.object](#).  
 diss dissimilarity (maybe NULL), see [partition.object](#).  
 call generating call, see [partition.object](#).  
 data (possibly standardized) see [partition.object](#).

## GENERATION

These objects are returned from [pam](#).

## METHODS

The "pam" class has methods for the following generic functions: print, summary.

## INHERITANCE

The class "pam" inherits from "partition". Therefore, the generic functions plot and clusplot can be used on a pam object.

## See Also

[pam](#), [dissimilarity.object](#), [partition.object](#), [plot.partition](#).

## Examples

```
## Use the silhouette widths for assessing the best number of clusters,
## following a one-dimensional example from Christian Hennig :
##
x <- c(rnorm(50), rnorm(50,mean=5), rnorm(30,mean=15))
asw <- numeric(20)
## Note that "k=1" won't work!
for (k in 2:20)
  asw[k] <- pam(x, k) $ silinfo $ avg.width
k.best <- which.max(asw)
cat("silhouette-optimal number of clusters:", k.best, "\n")

plot(1:20, asw, type="h", main = "pam() clustering assessment",
     xlab="k (# clusters)", ylab = "average silhouette width")
axis(1, k.best, paste("best",k.best,sep="\n"), col = "red", col.axis = "red")
```

---

partition.object    *Partitioning Object*

---

## Description

The objects of class "partition" represent a partitioning of a dataset into clusters.

**Value**

a "partition" object is a list with the following (and typically more) components:

clustering	the clustering vector. An integer vector of length $n$ , the number of observations, giving for each observation the number ('id') of the cluster to which it belongs.
call	the matched <code>call</code> generating the object.
silinfo	a list with all <i>silhouette</i> information, only available when the number of clusters is non-trivial, i.e., $1 < k < n$ and then has the following components, see <code>silhouette</code> <p><b>widths</b> an (<math>n \times 3</math>) matrix, as returned by <code>silhouette()</code>, with for each observation <math>i</math> the cluster to which <math>i</math> belongs, as well as the neighbor cluster of <math>i</math> (the cluster, not containing <math>i</math>, for which the average dissimilarity between its observations and <math>i</math> is minimal), and the silhouette width <math>s(i)</math> of the observation.</p> <p><b>clus.avg.widths</b> the average silhouette width per cluster.</p> <p><b>avg.width</b> the average silhouette width for the dataset, i.e., simply the average of <math>s(i)</math> over all observations <math>i</math>.</p> <p>This information is also needed to construct a <i>silhouette plot</i> of the clustering, see <code>plot.partition</code>.</p> <p>Note that <code>avg.width</code> can be maximized over different clusterings (e.g. with varying number of clusters) to choose an <i>optimal</i> clustering.</p>
objective	value of criterion maximized during the partitioning algorithm, may more than one entry for different stages.
diss	an object of class "dissimilarity", representing the total dissimilarity matrix of the dataset (or relevant subset, e.g. for <code>clara</code> ).
data	a matrix containing the original or standardized data. This might be missing to save memory or when a dissimilarity matrix was given as input structure to the clustering method.

**GENERATION**

These objects are returned from `pam`, `clara` or `fanny`.

**METHODS**

The "partition" class has a method for the following generic functions: `plot`, `clusplot`.

**INHERITANCE**

The following classes inherit from class "partition": "pam", "clara" and "fanny".

See `pam.object`, `clara.object` and `fanny.object` for details.

**See Also**

`pam`, `clara`, `fanny`.

---

 plantTraits

*Plant Species Traits Data*

---

**Description**

This dataset constitutes a description of 136 plant species according to biological attributes (morphological or reproductive)

**Usage**

```
data(plantTraits)
```

**Format**

A data frame with 136 observations on the following 31 variables.

pdias Diaspore mass (mg)

longindex Seed bank longevity

durflow Flowering duration

height Plant height, an ordered factor with levels 1 < 2 < ... < 8.

begflow Time of first flowering, an ordered factor with levels 1 < 2 < 3 < 4 < 5 < 6 < 7 < 8 < 9

mycor Mycorrhizas, an ordered factor with levels 0never < 1 sometimes < 2always

vegaer aerial vegetative propagation, an ordered factor with levels 0never < 1 present but limited < 2important.

vegsout underground vegetative propagation, an ordered factor with 3 levels identical to vegaer above.

autopoll selfing pollination, an ordered factor with levels 0never < 1rare < 2 often < the rule3

insects insect pollination, an ordered factor with 5 levels 0 < ... < 4.

wind wind pollination, an ordered factor with 5 levels 0 < ... < 4.

lign a binary factor with levels 0:1, indicating if plant is woody.

piq a binary factor indicating if plant is thorny.

ros a binary factor indicating if plant is rosette.

semiros semi-rosette plant, a binary factor (0: no; 1: yes).

leafy leafy plant, a binary factor.

suman summer annual, a binary factor.

winan winter annual, a binary factor.

monocarp monocarpic perennial, a binary factor.

polycarp polycarpic perennial, a binary factor.

seasaes seasonal aestival leaves, a binary factor.

seashiv seasonal hibernal leaves, a binary factor.

seasver seasonal vernal leaves, a binary factor.

everalw leaves always evergreen, a binary factor.

everparti leaves partially evergreen, a binary factor.

elaiio fruits with an elaiosome (dispersed by ants), a binary factor.

endozoo endozoochorous fruits, a binary factor.  
 epizoo epizoochorous fruits, a binary factor.  
 aquat aquatic dispersal fruits, a binary factor.  
 windgl wind dispersed fruits, a binary factor.  
 unsp unspecialized mechanism of seed dispersal, a binary factor.

### Details

Most of factor attributes are not disjunctive. For example, a plant can be usually pollinated by insects but sometimes self-pollination can occurred.

### Examples

```
data(plantTraits)

## Calculation of a dissimilarity matrix
library(cluster)
dai.b <- daisy(plantTraits,
              type = list(ordratio = 4:11, symm = 12:13, asymm = 14:31))

## Hierarchical classification
agn.trts <- agnes(dai.b, method="ward")
plot(agn.trts, which.plots = 2, cex= 0.6)
plot(agn.trts, which.plots = 1)
cutree6 <- cutree(agn.trts, k=6)
cutree6

## Principal Coordinate Analysis
cmds dai.b <- cmdscale(dai.b, k=6)
plot(cmdsdai.b[, 1:2], asp = 1, col = cutree6)
```

---

plot.agnes

*Plots of an Agglomerative Hierarchical Clustering*

---

### Description

Creates plots for visualizing an agnes object.

### Usage

```
## S3 method for class 'agnes':
plot(x, ask = FALSE, which.plots = NULL, main = NULL,
     sub = paste("Agglomerative Coefficient = ", round(x$ac, digits = 2)),
     adj = 0, nmax.lab = 35, max.strlen = 5, xax.pretty = TRUE, ...)
```

**Arguments**

<code>x</code>	an object of class "agnes", typically created by <code>agnes(.)</code> .
<code>ask</code>	logical; if true and <code>which.plots</code> is NULL, <code>plot.agnes</code> operates in interactive mode, via <code>menu</code> .
<code>which.plots</code>	integer vector or NULL (default), the latter producing both plots. Otherwise, <code>which.plots</code> must contain integers of 1 for a <i>banner</i> plot or 2 for a dendrogram or "clustering tree".
<code>main, sub</code>	main and sub title for the plot, with convenient defaults. See documentation for these arguments in <code>plot.default</code> .
<code>adj</code>	for label adjustment in <code>bannerplot()</code> .
<code>nmax.lab</code>	integer indicating the number of labels which is considered too large for single-name labelling the banner plot.
<code>max.strlen</code>	positive integer giving the length to which strings are truncated in banner plot labeling.
<code>xax.pretty</code>	logical or integer indicating if <code>pretty(*, n = xax.pretty)</code> should be used for the x axis. <code>xax.pretty = FALSE</code> is for back compatibility.
<code>...</code>	graphical parameters (see <code>par</code> ) may also be supplied and are passed to <code>bannerplot()</code> or <code>pltree()</code> (see <code>pltree.twins</code> ), respectively.

**Details**

When `ask = TRUE`, rather than producing each plot sequentially, `plot.agnes` displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted one must set `par(ask= TRUE)` before invoking the plot command.

The banner displays the hierarchy of clusters, and is equivalent to a tree. See Rousseeuw (1986) or chapter 5 of Kaufman and Rousseeuw (1990). The banner plots distances at which observations and clusters are merged. The observations are listed in the order found by the *agnes* algorithm, and the numbers in the `height` vector are represented as bars between the observations.

The leaves of the clustering tree are the original observations. Two branches come together at the distance between the two clusters being merged.

For more customization of the plots, rather call `bannerplot` and `pltree()`, i.e., its method `pltree.twins`, respectively.

directly with corresponding arguments, e.g., `xlab` or `ylab`.

**Side Effects**

Appropriate plots are produced on the current graphics device. This can be one or both of the following choices:

Banner  
Clustering tree

**Note**

In the banner plot, observation labels are only printed when the number of observations is limited less than `nmax.lab` (35, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.

For the dendrogram, more flexibility than via `pltree()` is provided by `dg <- as.dendrogram(x)` and plotting `dg` via `plot.dendrogram`.

## Examples

```
## Can also pass `labels` to pltree() and bannerplot():
data(iris)
cS <- as.character(Sp <- iris$Species)
cS[Sp == "setosa"] <- "S"
cS[Sp == "versicolor"] <- "V"
cS[Sp == "virginica"] <- "G"
ai <- agnes(iris[, 1:4])
plot(ai, labels = cS, nmax = 150) # bannerplot labels are mess
```

---

plot.diana

*Plots of a Divisive Hierarchical Clustering*

---

## Description

Creates plots for visualizing a diana object.

## Usage

```
## S3 method for class 'diana':
plot(x, ask = FALSE, which.plots = NULL, main = NULL,
      sub = paste("Divisive Coefficient = ", round(x$dc, digits = 2)),
      adj = 0, nmax.lab = 35, max.strlen = 5, xax.pretty = TRUE, ...)
```

## Arguments

- |             |   |
|-------------|---|
| x           | an object of class "diana", typically created by <a href="#">diana(.)</a> .   |
| ask         | logical; if true and which.plots is NULL, plot.diana operates in interactive mode, via <a href="#">menu</a> .   |
| which.plots | integer vector or NULL (default), the latter producing both plots. Otherwise, which.plots must contain integers of 1 for a <i>banner</i> plot or 2 for a dendrogram or “clustering tree”. |
| main, sub   | main and sub title for the plot, each with a convenient default. See documentation for these arguments in <a href="#">plot.default</a> .  |
| adj         | for label adjustment in <a href="#">bannerplot()</a> .  |

nmax.lab	integer indicating the number of labels which is considered too large for single-name labelling the banner plot.
max.strlen	positive integer giving the length to which strings are truncated in banner plot labeling.
xax.pretty	logical or integer indicating if <code>pretty(*, n = xax.pretty)</code> should be used for the x axis. <code>xax.pretty = FALSE</code> is for back compatibility.
...	graphical parameters (see <code>par</code> ) may also be supplied and are passed to <code>bannerplot()</code> or <code>pltree()</code> , respectively.

### Details

When `ask = TRUE`, rather than producing each plot sequentially, `plot.diana` displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted one must set `par(ask= TRUE)` before invoking the plot command.

The banner displays the hierarchy of clusters, and is equivalent to a tree. See Rousseeuw (1986) or chapter 6 of Kaufman and Rousseeuw (1990). The banner plots the diameter of each cluster being splitted. The observations are listed in the order found by the `diana` algorithm, and the numbers in the `height` vector are represented as bars between the observations.

The leaves of the clustering tree are the original observations. A branch splits up at the diameter of the cluster being splitted.

### Side Effects

An appropriate plot is produced on the current graphics device. This can be one or both of the following choices:

Banner  
Clustering tree

### Note

In the banner plot, observation labels are only printed when the number of observations is limited less than `nmax.lab` (35, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.

### References

see those in `plot.agnes`.

### See Also

`diana`, `diana.object`, `twins.object`, `par`.

### Examples

```
example(diana)# -> dv <- diana(...)

plot(dv, which = 1, nmax.lab = 100)

## wider labels :
op <- par(mar = par("mar") + c(0, 2, 0, 0))
plot(dv, which = 1, nmax.lab = 100, max.strlen = 12)
par(op)
```

---

plot.mona

*Banner of Monothetic Divisive Hierarchical Clusterings*

---

### Description

Creates the banner of a `mona` object.

### Usage

```
## S3 method for class 'mona':
plot(x, main = paste("Banner of ", deparse(x$call)),
      sub = NULL, xlab = "Separation step",
      col = c(2,0), axes = TRUE, adj = 0,
      nmax.lab = 35, max.strlen = 5, ...)
```

### Arguments

<code>x</code>	an object of class "mona", typically created by <code>mona(.)</code> .
<code>main, sub</code>	main and sub titles for the plot, with convenient defaults. See documentation in <a href="#">plot.default</a> .
<code>xlab</code>	x axis label, see <a href="#">title</a> .
<code>col, adj</code>	graphical parameters passed to <code>bannerplot()</code> .
<code>axes</code>	logical, indicating if (labeled) axes should be drawn.
<code>nmax.lab</code>	integer indicating the number of labels which is considered too large for labeling.
<code>max.strlen</code>	positive integer giving the length to which strings are truncated in labeling.
<code>...</code>	further graphical arguments are passed to <code>bannerplot()</code> and <code>text</code> .

### Details

Plots the separation step at which clusters are splitted. The observations are given in the order found by the `mona` algorithm, the numbers in the `step` vector are represented as bars between the observations.

When a long bar is drawn between two observations, those observations have the same value for each variable. See chapter 7 of Kaufman and Rousseeuw (1990).

### Side Effects

A banner is plotted on the current graphics device.

### Note

In the banner plot, observation labels are only printed when the number of observations is limited less than `nmax.lab` (35, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.

### References

see those in [plot.agnes](#).

---

plot.partition      *Plot of a Partition of the Data Set*

---

**Description**

Creates plots for visualizing a `partition` object.

**Usage**

```
## S3 method for class 'partition':
plot(x, ask = FALSE, which.plots = NULL,
     nmax.lab = 40, max.strlen = 5, data = x$data, dist = NULL,
     cor = TRUE, stand = FALSE, lines = 2,
     shade = FALSE, color = FALSE, labels = 0, plotchar = TRUE,
     span = TRUE, xlim = NULL, ylim = NULL, main = NULL, ...)
```

**Arguments**

<code>x</code>	an object of class "partition", typically created by the functions <a href="#">pam</a> , <a href="#">clara</a> , or <a href="#">fanny</a> .
<code>ask</code>	logical; if true and <code>which.plots</code> is NULL, <code>plot.partition</code> operates in interactive mode, via <a href="#">menu</a> .
<code>which.plots</code>	integer vector or NULL (default), the latter producing both plots. Otherwise, <code>which.plots</code> must contain integers of 1 for a <i>clusplot</i> or 2 for <i>silhouette</i> .
<code>nmax.lab</code>	integer indicating the number of labels which is considered too large for single-name labeling the silhouette plot.
<code>max.strlen</code>	positive integer giving the length to which strings are truncated in silhouette plot labeling.
<code>data</code>	numeric matrix with the scaled data; per default taken from the partition object <code>x</code> , but can be specified explicitly.
<code>dist</code>	when <code>x</code> does not have a <code>diss</code> component as for <a href="#">pam</a> (*, <code>keep.diss=FALSE</code> ), <code>dist</code> must be the dissimilarity if a <i>clusplot</i> is desired.
<code>cor, stand, lines, shade, color, labels, plotchar, span, xlim, ylim, main, ...</code>	All optional arguments available for the <a href="#">clusplot.default</a> function (except for the <code>diss</code> one) and graphical parameters (see <a href="#">par</a> ) may also be supplied as arguments to this function.

**Details**

When `ask= TRUE`, rather than producing each plot sequentially, `plot.partition` displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted, call `par(ask= TRUE)` before invoking the plot command.

The *clusplot* of a cluster partition consists of a two-dimensional representation of the observations, in which the clusters are indicated by ellipses (see [clusplot.partition](#) for more details).

The *silhouette plot* of a nonhierarchical clustering is fully described in Rousseeuw (1987) and in chapter 2 of Kaufman and Rousseeuw (1990). For each observation  $i$ , a bar is drawn, representing its silhouette width  $s(i)$ , see [silhouette](#) for details. Observations are grouped per cluster, starting with cluster 1 at the top. Observations with a large  $s(i)$  (almost 1) are very well clustered, a small  $s(i)$  (around 0) means that the observation lies between two clusters, and observations with a negative  $s(i)$  are probably placed in the wrong cluster.

A clustering can be performed for several values of  $k$  (the number of clusters). Finally, choose the value of  $k$  with the largest overall average silhouette width.

### Side Effects

An appropriate plot is produced on the current graphics device. This can be one or both of the following choices:

Clusplot  
Silhouette plot

### Note

In the silhouette plot, observation labels are only printed when the number of observations is less than `nmax.lab` (40, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.

For more flexibility, use `plot(silhouette(x), ...)`, see [plot.silhouette](#).

### Examples

```
## generate 25 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)),
           cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))
plot(pam(x, 2))

## Save space not keeping data in clus.object, and still clusplot() it:
data(xclara)
cx <- clara(xclara, 3, keep.data = FALSE)
cx$data # is NULL
plot(cx, data = xclara)
```

---

 pltree

*Clustering Trees - Generic Function*

---

**Description**

Generic function drawing a clustering tree (“dendrogram”) on the current graphics device. There is a `twins` method, see `pltree.twins` for usage and examples.

**Usage**

```
pltree(x, ...)
```

**Arguments**

`x` an R object (for which a `pltree` method is defined).

`...` methods may have additional arguments. Graphical parameters (see `par`) may also be supplied as arguments to this function.

**See Also**

`pltree.twins`, `twins.object`.

---

 pltree.twins

*Clustering Tree of a Hierarchical Clustering*

---

**Description**

Draws a clustering tree (dendrogram) of a `twins` object, i.e., hierarchical clustering, typically resulting from `agnes()` or `diana()`.

**Usage**

```
## S3 method for class 'twins':
pltree(x, main = paste("Dendrogram of ", deparse(x$call)),
       labels = NULL, ylab = "Height", ...)
```

**Arguments**

`x` an object of class "twins", typically created by either `agnes()` or `diana()`.

`main` main title with a sensible default.

`labels` labels to use; the default is constructed from `x`.

`ylab` label for y-axis.

`...` graphical parameters (see `par`) may also be supplied as arguments to this function.

**Details**

Creates a plot of a clustering tree given a `twins` object. The leaves of the tree are the original observations. In case of an agglomerative clustering, two branches come together at the distance between the two clusters being merged. For a divisive clustering, a branch splits up at the diameter of the cluster being splitted.

Note that currently the method function simply calls `plot(as.hclust(x), ...)`, which dispatches to `plot.hclust(...)`. If more flexible plots are needed, consider `xx <- as.dendrogram(as.hclust(x))` and plotting `xx`, see `plot.dendrogram`.

**Value**

a NULL value is returned.

**See Also**

`agnes`, `agnes.object`, `diana`, `diana.object`, `hclust`, `par`, `plot.agnes`, `plot.diana`.

**Examples**

```
data(votes.repub)
agn <- agnes(votes.repub)
pltree(agn)

dagn <- as.dendrogram(as.hclust(agn))
dagn2 <- as.dendrogram(as.hclust(agn), hang = 0.2)
op <- par(mar = par("mar") + c(0,0,0, 2)) # more space to the right
plot(dagn2, horiz = TRUE)
plot(dagn, horiz = TRUE, center = TRUE,
      nodePar = list(lab.cex = 0.6, lab.col = "forest green", pch = NA),
      main = deparse(agn$call))
par(op)
```

---

pluton

*Isotopic Composition Plutonium Batches*

---

**Description**

The `pluton` data frame has 45 rows and 4 columns, containing percentages of isotopic composition of 45 Plutonium batches.

**Usage**

```
data(pluton)
```

**Format**

This data frame contains the following columns:

**Pu238** the percentages of  $^{238}\text{Pu}$ , always less than 2 percent.

**Pu239** the percentages of  $^{239}\text{Pu}$ , typically between 60 and 80 percent (from neutron capture of Uranium,  $^{238}\text{U}$ ).

**Pu240** percentage of the plutonium 240 isotope.

**Pu241** percentage of the plutonium 241 isotope.

### Details

Note that the percentage of plutonium-242 can be computed from the other four percentages, see the examples.

In the reference below it is explained why it is very desirable to combine these plutonium patches in three groups of similar size.

### Source

Available as 'pluton.dat' from the archive

currently <http://www.agoras.ua.ac.be/datasets/clusplot-examples.tar.gz>.

### References

Rousseeuw, P.J. and Kaufman, L and Trauwaert, E. (1996) Fuzzy clustering using scatter matrices, *Computational Statistics and Data Analysis* **23**(1), 135–151.

### Examples

```
data(pluton)

hist(apply(pluton,1,sum), col = "gray") # between 94% and 100%
pu5 <- pluton
pu5$Pu242 <- 100 - apply(pluton,1,sum) # the remaining isotope.
pairs(pu5)
```

---

predict.ellipsoid *Predict Method for Ellipsoid Objects*

---

### Description

Compute points on the ellipsoid boundary, mostly for drawing.

### Usage

```
predict.ellipsoid(object, n.out=201, ...)
## S3 method for class 'ellipsoid':
predict(object, n.out=201, ...)
ellipsoidPoints(A, d2, loc, n.half = 201)
```

### Arguments

object	an object of class <code>ellipsoid</code> , typically from <code>ellipsoidhull()</code> ; alternatively any list-like object with proper components, see details below.
n.out, n.half	half the number of points to create.
A, d2, loc	arguments of the auxiliary <code>ellipsoidPoints</code> , see below.
...	passed to and from methods.

**Details**

Note `ellipsoidPoints` is the workhorse function of `predict.ellipsoid` a standalone function and method for `ellipsoid` objects, see [ellipsoidhull](#). The class of object is not checked; it must solely have valid components `loc` (length  $p$ ), the  $p \times p$  matrix `cov` (corresponding to  $A$ ) and `d2` for the center, the shape (“covariance”) matrix and the squared average radius (or distance) or `qchisq`(\*,  $p$ ) quantile.

Unfortunately, this is only implemented for  $p = 2$ , currently; contributions for  $p \geq 3$  are *very welcome*.

**Value**

a numeric matrix of dimension  $2 * n.out$  times  $p$ .

**See Also**

[ellipsoidhull](#), [volume.ellipsoid](#).

**Examples**

```
## see also example(ellipsoidhull)

## Robust vs. L.S. covariance matrix
set.seed(143)
x <- rt(200, df=3)
y <- 3*x + rt(200, df=2)
plot(x,y, main="non-normal data (N=200)")
mtext("with classical and robust cov.matrix ellipsoids")
X <- cbind(x,y)
C.ls <- cov(X) ; m.ls <- colMeans(X)
d2.99 <- qchisq(0.99, df = 2)
lines(ellipsoidPoints(C.ls, d2.99, loc=m.ls), col="green")
if(require(MASS)) {
  Cxy <- cov.rob(cbind(x,y))
  lines(ellipsoidPoints(Cxy$cov, d2 = d2.99, loc=Cxy$center), col="red")
}# MASS
```

---

print.agnes

*Print Method for AGNES Objects*

---

**Description**

Prints the call, agglomerative coefficient, ordering of objects and distances between merging clusters (‘Height’) of an `agnes` object.

This is a method for the generic `print()` function for objects inheriting from class `agnes`, see [agnes.object](#).

**Usage**

```
## S3 method for class 'agnes':
print(x, ...)
```

**Arguments**

x                    an agnes object.  
...                   potential further arguments (required by generic).

**See Also**

[summary.agnes](#) producing more output; [agnes](#), [agnes.object](#), [print](#),  
[print.default](#).

---

print.clara                    *Print Method for CLARA Objects*

---

**Description**

Prints the best sample, medoids, clustering vector and objective function of clara object.  
This is a method for the function [print \(\)](#) for objects inheriting from class [clara](#).

**Usage**

```
## S3 method for class 'clara':  
print(x, ...)
```

**Arguments**

x                    a clara object.  
...                   potential further arguments (require by generic).

**See Also**

[summary.clara](#) producing more output; [clara](#), [clara.object](#), [print](#),  
[print.default](#).

---

print.diana                    *Print Method for DIANA Objects*

---

**Description**

Prints the ordering of objects, diameters of splitted clusters, and divisive coefficient of a diana object.  
This is a method for the function [print \(\)](#) for objects inheriting from class [diana](#).

**Usage**

```
## S3 method for class 'diana':  
print(x, ...)
```

**Arguments**

`x` a diana object.  
`...` potential further arguments (require by generic).

**See Also**

[diana](#), [diana.object](#), [print](#), [print.default](#).

---

```
print.dissimilarity
```

*Print and Summary Methods for Dissimilarity Objects*

---

**Description**

Print or summarize the distances and the attributes of a dissimilarity object.

These are methods for the functions `print()` and `summary()` for dissimilarity objects.

See `print`, `print.default`, or `summary` for the general behavior of these.

**Usage**

```
## S3 method for class 'dissimilarity':
print(x, diag = NULL, upper = NULL,
      digits = getOption("digits"), justify = "none", right = TRUE, ...)
## S3 method for class 'dissimilarity':
summary(object,
        digits = max(3, getOption("digits") - 2), ...)
## S3 method for class 'summary.dissimilarity':
print(x, ...)
```

**Arguments**

`x`, `object` a dissimilarity object or a `summary.dissimilarity` one for `print.summary.dissimilarity()`.

`digits` the number of digits to use, see [print.default](#).

`diag`, `upper`, `justify`, `right` optional arguments specifying how the triangular dissimilarity matrix is printed; see [print.dist](#).

`...` potential further arguments (require by generic).

**See Also**

[daisy](#), [dissimilarity.object](#), [print](#), [print.default](#), [print.dist](#).

**Examples**

```
## See example(daisy)

sd <- summary(daisy(matrix(rnorm(100), 20, 5)))
sd # -> print.summary.dissimilarity(.)
str(sd)
```

---

`print.fanny`*Print and Summary Methods for FANNY Objects*

---

**Description**

Prints the objective function, membership coefficients and clustering vector of `fanny` object.

This is a method for the function `print ()` for objects inheriting from class `fanny`.

**Usage**

```
## S3 method for class 'fanny':
print(x, digits = getOption("digits"), ...)
## S3 method for class 'fanny':
summary(object, ...)
## S3 method for class 'summary.fanny':
print(x, digits = getOption("digits"), ...)
```

**Arguments**

`x`, `object`      a `fanny` object.  
`digits`            number of significant digits for printing, see `print.default`.  
`...`              potential further arguments (required by generic).

**See Also**

`fanny`, `fanny.object`, `print`, `print.default`.

---

`print.mona`*Print Method for MONA Objects*

---

**Description**

Prints the ordering of objects, separation steps, and used variables of a `mona` object.

This is a method for the function `print ()` for objects inheriting from class `mona`.

**Usage**

```
## S3 method for class 'mona':
print(x, ...)
```

**Arguments**

`x`                    a `mona` object.  
`...`                potential further arguments (require by generic).

**See Also**

`mona`, `mona.object`, `print`, `print.default`.

---

`print.pam`*Print Method for PAM Objects*

---

**Description**

Prints the medoids, clustering vector and objective function of `pam` object.

This is a method for the function `print()` for objects inheriting from class `pam`.

**Usage**

```
## S3 method for class 'pam':  
print(x, ...)
```

**Arguments**

`x` a `pam` object.  
`...` potential further arguments (require by generic).

**See Also**

`pam`, `pam.object`, `print`, `print.default`.

---

`ruspini`*Ruspini Data*

---

**Description**

The Ruspini data set, consisting of 75 points in four groups that is popular for illustrating clustering techniques.

**Usage**

```
data(ruspini)
```

**Format**

A data frame with 75 observations on 2 variables giving the x and y coordinates of the points, respectively.

**Source**

E. H. Ruspini (1970): Numerical methods for fuzzy clustering. *Inform. Sci.*, **2**, 319–350.

**References**

Anja Struyf, Mia Hubert & Peter J. Rousseeuw (1996): Clustering in an Object-Oriented Environment. *Journal of Statistical Software*, **1**. <http://www.stat.ucla.edu/journals/jss/>

**Examples**

```

data(ruspini)

## Plot similar to Figure 4 in Stryuf et al (1996)
## Not run: plot(pam(ruspini, 4), ask = TRUE)

## Plot similar to Figure 6 in Stryuf et al (1996)
plot(fanny(ruspini, 5))

```

silhouette

*Compute or Extract Silhouette Information from Clustering***Description**

Compute silhouette information according to a given clustering in  $k$  clusters.

**Usage**

```

silhouette(x, ...)
## Default S3 method:
silhouette(x, dist, dmatrix, ...)
## S3 method for class 'partition':
silhouette(x, ...)
## S3 method for class 'clara':
silhouette(x, full = FALSE, ...)

sortSilhouette(object, ...)
## S3 method for class 'silhouette':
summary(object, FUN = mean, ...)
## S3 method for class 'silhouette':
plot(x, nmax.lab = 40, max.strlen = 5,
     main = NULL, sub = NULL, xlab = expression("Silhouette width "* s[i]),
     col = "gray", do.col.sort = length(col) > 1, border = 0,
     cex.names = par("cex.axis"), do.n.k = TRUE, do.clus.stat = TRUE, ...)

```

**Arguments**

<code>x</code>	an object of appropriate class; for the default method an integer vector with $k$ different integer cluster codes or a list with such an <code>x\$clustering</code> component. Note that silhouette statistics are only defined if $2 \leq k \leq n - 1$ .
<code>dist</code>	a dissimilarity object inheriting from class <code>dist</code> or coercible to one. If not specified, <code>dmatrix</code> must be.
<code>dmatrix</code>	a symmetric dissimilarity matrix ( $n \times n$ ), specified instead of <code>dist</code> , which can be more efficient.
<code>full</code>	logical specifying if a <i>full</i> silhouette should be computed for <code>clara</code> object. Note that this requires $O(n^2)$ memory, since the full dissimilarity (see <code>daisy</code> ) is needed internally.
<code>object</code>	an object of class <code>silhouette</code> .
<code>...</code>	further arguments passed to and from methods.

<code>FUN</code>	function used to summarize silhouette widths.
<code>nmax.lab</code>	integer indicating the number of labels which is considered too large for single-name labeling the silhouette plot.
<code>max.strlen</code>	positive integer giving the length to which strings are truncated in silhouette plot labeling.
<code>main, sub, xlab</code>	arguments to <code>title</code> ; have a sensible non-NULL default here.
<code>col, border, cex.names</code>	arguments passed <code>barplot()</code> ; note that the default used to be <code>col = heat.colors(n)</code> , <code>border = par("fg")</code> instead. <code>col</code> can also be a color vector of length $k$ for clusterwise coloring, see also <code>do.col.sort</code> :
<code>do.col.sort</code>	logical indicating if the colors <code>col</code> should be sorted “along” the silhouette; this is useful for casewise or clusterwise coloring.
<code>do.n.k</code>	logical indicating if $n$ and $k$ “title text” should be written.
<code>do.clus.stat</code>	logical indicating if cluster size and averages should be written right to the silhouettes.

### Details

For each observation  $i$ , the *silhouette width*  $s(i)$  is defined as follows:

Put  $a(i)$  = average dissimilarity between  $i$  and all other points of the cluster to which  $i$  belongs (if  $i$  is the *only* observation in its cluster,  $s(i) := 0$  without further calculations). For all *other* clusters  $C$ , put  $d(i, C)$  = average dissimilarity of  $i$  to all observations of  $C$ . The smallest of these  $d(i, C)$  is  $b(i) := \min_C d(i, C)$ , and can be seen as the dissimilarity between  $i$  and its “neighbor” cluster, i.e., the nearest one to which it does *not* belong. Finally,

$$s(i) := \frac{b(i) - a(i)}{\max(a(i), b(i))}.$$

`silhouette.default()` is now based on C code donated by Romain Francois (the R version being still available as `cluster:::silhouette.default.R`).

Observations with a large  $s(i)$  (almost 1) are very well clustered, a small  $s(i)$  (around 0) means that the observation lies between two clusters, and observations with a negative  $s(i)$  are probably placed in the wrong cluster.

### Value

`silhouette()` returns an object, `sil`, of class `silhouette` which is an  $[n \times 3]$  matrix with attributes. For each observation  $i$ , `sil[i, ]` contains the cluster to which  $i$  belongs as well as the neighbor cluster of  $i$  (the cluster, not containing  $i$ , for which the average dissimilarity between its observations and  $i$  is minimal), and the silhouette width  $s(i)$  of the observation. The `colnames` correspondingly are `c("cluster", "neighbor", "sil_width")`.

`summary(sil)` returns an object of class `summary.silhouette`, a list with components

<code>si.summary</code>	numerical <a href="#">summary</a> of the individual silhouette widths $s(i)$ .
<code>clus.avg.widths</code>	numeric (rank 1) array of clusterwise <i>means</i> of silhouette widths where <code>mean = FUN</code> is used.
<code>avg.width</code>	the total mean <code>FUN(s)</code> where $s$ are the individual silhouette widths.

clus.sizes    [table](#) of the  $k$  cluster sizes.  
 call         if available, the call creating `sil`.  
 Ordered      logical identical to `attr(sil, "Ordered")`, see below.

`sortSilhouette(sil)` orders the rows of `sil` as in the silhouette plot, by cluster (increasingly) and decreasing silhouette width  $s(i)$ .

`attr(sil, "Ordered")` is a logical indicating if `sil` is ordered as by `sortSilhouette()`. In that case, `rownames(sil)` will contain case labels or numbers, and

`attr(sil, "iOrd")` the ordering index vector.

### Note

While `silhouette()` is *intrinsic* to the [partition](#) clusterings, and hence has a (trivial) method for these, it is straightforward to get silhouettes from hierarchical clusterings from `silhouette.default()` with `cutree()` and distance as input.

By default, for `clara()` partitions, the silhouette is just for the best random *subset* used. Use `full = TRUE` to compute (and later possibly plot) the full silhouette.

### Examples

```
data(ruspini)
pr4 <- pam(ruspini, 4)
str(si <- silhouette(pr4))
(ssi <- summary(si))
plot(si) # silhouette plot
plot(si, col = c("red", "green", "blue", "purple"))# with cluster-wise coloring

si2 <- silhouette(pr4$clustering, dist(ruspini, "canberra"))
summary(si2) # has small values: "canberra"'s fault
plot(si2, nmax= 80, cex.names=0.6)

op <- par(mfrow= c(3,2), oma= c(0,0, 3, 0),
          mgp= c(1.6, .8, 0), mar= .1+c(4,2,2,2))
for(k in 2:6)
  plot(silhouette(pam(ruspini, k=k)), main = paste("k = ",k), do.n.k=FALSE)
mtext("PAM(Ruspini) as in Kaufman & Rousseeuw, p.101",
      outer = TRUE, font = par("font.main"), cex = par("cex.main"))
par(op)

## clara(): standard silhouette is just for the best random subset
data(xclara)
set.seed(7)
str(xclk <- xclara[sample(nrow(xclara), size = 1000) ,])
```

```

cl3 <- clara(xclk, 3)
plot(silhouette(cl3)) # only of the "best" subset of 46
## The full silhouette: internally needs large (36 MB) dist object:
sf <- silhouette(cl3, full = TRUE) ## this is the same as
s.full <- silhouette(cl3$clustering, daisy(xclk))
if(paste(R.version$major, R.version$minor, sep=".") >= "2.3.0")
  stopifnot(all.equal(sf, s.full, check.attributes = FALSE, tol = 0))
## color dependent on original "3 groups of each 1000":
plot(sf, col = 2+ as.integer(names(cl3$clustering) ) %% 1000,
      main ="plot(silhouette(clara(.), full = TRUE))")

## Silhouette for a hierarchical clustering:
ar <- agnes(ruspini)
si3 <- silhouette(cutree(ar, k = 5), # k = 4 gave the same as pam() above
                 daisy(ruspini))
plot(si3, nmax = 80, cex.names = 0.5)
## 2 groups: Agnes() wasn't too good:
si4 <- silhouette(cutree(ar, k = 2), daisy(ruspini))
plot(si4, nmax = 80, cex.names = 0.5)

```

sizeDiss

*Sample Size of Dissimilarity Like Object***Description**

Returns the number of observations (*sample size*) corresponding to a dissimilarity like object, or equivalently, the number of rows or columns of a matrix when only the lower or upper triangular part (without diagonal) is given.

It is nothing else but the inverse function of  $f(n) = n(n - 1)/2$ .

**Usage**

```
sizeDiss(d)
```

**Arguments**

**d** any R object with length (typically)  $n(n - 1)/2$ .

**Value**

a number;  $n$  if length(d) ==  $n(n-1)/2$ , NA otherwise.

**See Also**

[dissimilarity.object](#) and also [as.dist](#) for class dissimilarity and dist objects which have a Size attribute.

**Examples**

```

sizeDiss(1:10) # 5, since 10 == 5 * (5 - 1) / 2
sizeDiss(1:9) # NA

n <- 1:100
stopifnot(n == sapply( n*(n-1)/2, function(n) sizeDiss(logical(n))))

```

---

summary.agnes	<i>Summary Method for 'agnes' Objects</i>
---------------	---

---

### Description

Returns (and prints) a summary list for an `agnes` object. Printing gives more output than the corresponding `print.agnes` method.

### Usage

```
## S3 method for class 'agnes':
summary(object, ...)
## S3 method for class 'summary.agnes':
print(x, ...)
```

### Arguments

`x`, `object`     a `agnes` object.  
`...`             potential further arguments (require by generic).

### See Also

`agnes`, `agnes.object`.

### Examples

```
data(agriculture)
summary(agnes(agriculture))
```

---

summary.clara	<i>Summary Method for 'clara' Objects</i>
---------------	---

---

### Description

Returns (and prints) a summary list for a `clara` object. Printing gives more output than the corresponding `print.clara` method.

### Usage

```
## S3 method for class 'clara':
summary(object, ...)
## S3 method for class 'summary.clara':
print(x, ...)
```

### Arguments

`x`, `object`     a `clara` object.  
`...`             potential further arguments (require by generic).

**See Also**

[clara.object](#)

**Examples**

```
## generate 2000 objects, divided into 5 clusters.
set.seed(47)
x <- rbind(cbind(rnorm(400, 0,4), rnorm(400, 0,4)),
           cbind(rnorm(400,10,8), rnorm(400,40,6)),
           cbind(rnorm(400,30,4), rnorm(400, 0,4)),
           cbind(rnorm(400,40,4), rnorm(400,20,2)),
           cbind(rnorm(400,50,4), rnorm(400,50,4))
)
clx5 <- clara(x, 5)
## Mis`classification' table:

table(rep(1:5, rep(400,5)), clx5$clust) # -> 1 "error"
summary(clx5)

## Graphically:
par(mfrow = c(3,1), mgp = c(1.5, 0.6, 0), mar = par("mar") - c(0,0,2,0))

plot(x, col = rep(2:6, rep(400,5)))
plot(clx5)
```

---

summary.diana

*Summary Method for 'diana' Objects*

---

**Description**

Returns (and prints) a summary list for a diana object.

**Usage**

```
## S3 method for class 'diana':
summary(object, ...)
## S3 method for class 'summary.diana':
print(x, ...)
```

**Arguments**

`x`, `object`     a [diana](#) object.  
`...`             potential further arguments (require by generic).

**See Also**

[diana](#), [diana.object](#).

---

`summary.mona`*Summary Method for 'mona' Objects*

---

**Description**

Returns (and prints) a summary list for a mona object.

**Usage**

```
## S3 method for class 'mona':  
summary(object, ...)  
## S3 method for class 'summary.mona':  
print(x, ...)
```

**Arguments**

`x, object` a [mona](#) object.  
`...` potential further arguments (require by generic).

**See Also**

[mona](#), [mona.object](#).

---

`summary.pam`*Summary Method for PAM Objects*

---

**Description**

Summarize a [pam](#) object and return an object of class `summary.pam`. There's a [print](#) method for the latter.

**Usage**

```
## S3 method for class 'pam':  
summary(object, ...)  
## S3 method for class 'summary.pam':  
print(x, ...)
```

**Arguments**

`x, object` a [pam](#) object.  
`...` potential further arguments (require by generic).

**See Also**

[pam](#), [pam.object](#).

---

`twins.object`      *Hierarchical Clustering Object*

---

**Description**

The objects of class "twins" represent an agglomerative or divisive (polythetic) hierarchical clustering of a dataset.

**Value**

See [agnes.object](#) and [diana.object](#) for details.

**GENERATION**

This class of objects is returned from `agnes` or `diana`.

**METHODS**

The "twins" class has a method for the following generic function: `pltree`.

**INHERITANCE**

The following classes inherit from class "twins": "agnes" and "diana".

**See Also**

[agnes,diana](#).

---

`volume.ellipsoid`      *Compute the Volume of Planar Object*

---

**Description**

Compute the volume of a planar object. This is a generic function and a method for `ellipsoid` objects.

**Usage**

```
## S3 method for class 'ellipsoid':
volume(object)
```

**Arguments**

`object`      an R object the volume of which is wanted; for the `ellipsoid` method, an object of that class (see [ellipsoidhull](#) or the example below).

**Value**

a number, the volume of the given object.

**See Also**

`ellipsoidhull` for spanning ellipsoid computation.

**Examples**

```
## example(ellipsoidhull) # which defines `ellipsoid' object <namefoo>
myEl <- structure(list(cov = rbind(c(3,1),1:2), loc = c(0,0), d2 = 10),
                  class = "ellipsoid")
volume(myEl) # i.e. "area" here (d = 2)
myEl # also mentions the "volume"
```

---

votes.repub

*Votes for Republican Candidate in Presidential Elections*

---

**Description**

A data frame with the percents of votes given to the republican candidate in presidential elections from 1856 to 1976. Rows represent the 50 states, and columns the 31 elections.

**Usage**

```
data(votes.repub)
```

**Source**

S. Peterson (1973): *A Statistical History of the American Presidential Elections*. New York: Frederick Ungar Publishing Co.

Data from 1964 to 1976 is from R. M. Scammon, *American Votes 12*, Congressional Quarterly.

---

xclara

*Bivariate Data Set with 3 Clusters*

---

**Description**

An artificial data set consisting of 3000 points in 3 well-separated clusters of size 1000 each.

**Usage**

```
data(xclara)
```

**Format**

A data frame with 3000 observations on 2 numeric variables giving the  $x$  and  $y$  coordinates of the points, respectively.

**Source**

Sample data set accompanying the reference below, obtained from <http://www.stat.ucla.edu/journals/jss/v01/i04/data/>.

## Chapter 16

# The foreign package

---

lookup.xport

*Lookup Information on a SAS XPORT Format Library*

---

### Description

Scans a file as a SAS XPORT format library and returns a list containing information about the SAS library.

### Usage

```
lookup.xport (file)
```

### Arguments

file	character variable with the name of the file to read. The file must be in SAS XPORT format.
------	---

### Value

A list with one component for each dataset in the XPORT format library.

### Author(s)

Saikat DebRoy

### References

SAS Technical Support document TS-140: “The Record Layout of a Data Set in SAS Transport (XPORT) Format” available as <http://ftp.sas.com/techsup/download/technote/ts140.html>.

### See Also

**Examples**

```
## Not run:  
lookup.xport("transport")  
  
## End(Not run)
```

---

read.arff                      *Read Data from ARFF Files*

---

**Description**

Reads data from Weka Attribute-Relation File Format (ARFF) files.

**Usage**

```
read.arff(file)
```

**Arguments**

`file`                      a character string with the name of the ARFF file to read from, or a [connection](#) which will be opened if necessary, and if so closed at the end of the function call.

**Value**

A data frame containing the data from the ARFF file.

**References**

Attribute-Relation File Format <http://www.cs.waikato.ac.nz/~ml/weka/arff.html>  
[http://weka.sourceforge.net/wekadoc/index.php/en:ARFF\\_\(3.5.1\)](http://weka.sourceforge.net/wekadoc/index.php/en:ARFF_(3.5.1))

---

read.dbf                      *Read a DBF File*

---

**Description**

The function reads a DBF file into a data frame, converting character fields to factors, and trying to respect NULL fields.

**Usage**

```
read.dbf(file, as.is = FALSE)
```

## Arguments

<code>file</code>	name of input file
<code>as.is</code>	should character vectors not be converted to factors?

## Details

DBF is the extension used for files written for the 'XBASE' family of database languages, 'covering the dBase, Clipper, FoxPro, and their Windows equivalents Visual dBase, Visual Objects, and Visual FoxPro, plus some older products' (<http://www.clicketyclick.dk/databases/xbase/format/>). Most of these follow the file structure used by Ashton-Tate's dBase II, III or 4 (later owned by Borland).

`read.dbf` is based on C code from <http://shapelib.maptools.org/> which implements the 'XBASE' specification. It can convert fields of type "L" (logical), "N" and "F" (numeric and float) and "D" (dates): all other field types are read as-is as character vectors. A numeric field is read as an R integer vector if it is encoded to have no decimals, otherwise as a numeric vector. However, if the numbers are too large to fit into an integer vector, it is changed to numeric. Note that it is possible to read integers that cannot be represented exactly even as doubles: this sometimes occurs if IDs are incorrectly coded as numeric.

## Value

A data frame of data from the DBF file; note that the field names are adjusted to use in R using `make.names(unique=TRUE)`.

There is an attribute `"data_type"` giving the single-character dBase types for each field.

## Author(s)

Nicholas Lewin-Koh and Roger Bivand; shapelib by Frank Warmerdam

## References

str(x)
summary(x)
```

read.dta

*Read Stata Binary Files***Description**

Reads a file in Stata version 5–11 binary format into a data frame.

**Usage**

```
read.dta(file, convert.dates = TRUE, convert.factors = TRUE,
         missing.type = FALSE,
         convert.underscore = FALSE, warn.missing.labels = TRUE)
```

**Arguments**

`file` a filename or URL as a character string.

`convert.dates` Convert Stata dates to Date class?

`convert.factors` Use Stata value labels to create factors? (version 6.0 or later).

`missing.type` For version 8 or later, store information about different types of missing data?

`convert.underscore` Convert "\_" in Stata variable names to "." in R names?

`warn.missing.labels` Warn if a variable is specified with value labels and those value labels are not present in the file.

**Details**

If the filename appears to be a URL (of schemes 'http:', 'ftp:' or 'https:') the URL is first downloaded to a temporary file and then read. ('https:' is only supported on some platforms.)

The variables in the Stata data set become the columns of the data frame. Missing values are correctly handled. The data label, variable labels, and timestamp are stored as attributes of the data frame. Nothing is done with variable characteristics.

By default Stata dates (%d and %td formats) are converted to R's Date class and variables with Stata value labels are converted to factors. Ordinarily, read.dta will not convert a variable to a factor unless a label is present for every level. Use convert.factors = NA to override this. In any case the value label and format information is stored as attributes on the returned data frame.

Stata 8.0 introduced a system of 27 different missing data values. If missing.type is TRUE a separate list is created with the same variable names as the loaded data. For string variables the list value is NULL. For other variables the value is NA where the observation is not missing and 0–26 when the observation is missing. This is attached as the "missing" attribute of the returned value.

**Value**

A data frame with attributes. These will include "datalabel", "time.stamp", "formats", "types", "val.labels", "var.labels" and "version" and may include "label.table". Possible versions are 5, 6, 7, -7 (Stata 7SE, 'format-111'), 8 (Stata 8 and 9, 'format-113') and 10 (Stata 10 and 11, 'format-114').

The value labels in attribute "val.labels" name a table for each variable, or are an empty string. The tables are elements of the named list attribute "label.table": each is an integer vector with names,

### Examples

```
data(swiss)
write.dta(swiss,swissfile <- tempfile())
read.dta(swissfile)
```

---

read.epiinfo            *Read Epi Info Data Files*

---

### Description

Reads data files in the .REC format used by Epi Info versions 6 and earlier and by EpiData. Epi Info is a public domain database and statistics package produced by the US Centers for Disease Control and EpiData is a freely available data entry and validation system.

### Usage

```
read.epiinfo(file, read.deleted = FALSE, guess.broken.dates = FALSE,
             thisyear = NULL, lower.case.names = FALSE)
```

### Arguments

`file`            A filename, URL, or connection.

`read.deleted` Deleted records are read if TRUE, omitted if FALSE or replaced with NA if NA.

`guess.broken.dates` Attempt to convert dates with 0 or 2 digit year information (see 'Details').

`thisyear`        A 4-digit year to use for dates with no year. Defaults to the current year.

`lower.case.names` Convert variable names to lowercase?

## Details

Epi Info allows dates to be specified with no year or with a 2 or 4 digits. Dates with four-digit years are always converted to `Date` class. With the `guess.broken.dates` option the function will attempt to convert two-digit years using the operating system's default method (see [Date](#)) and will use the current year or the `thisyear` argument for dates with no year information.

If `read.deleted` is `TRUE` the "deleted" attribute of the data frame indicates the deleted records.

## Value

A data frame.

## Note

Epi Info 2000, the current version, uses the Microsoft Access file format to store data. This may be readable with the `RODBC` or `RDCOM` packages.

## Examples

```
## Not run:
data<-read.epiinfo("oswego.rec",guess.broken.dates=TRUE,thisyear="1972")

## End(Not run)
```

---

read.mtp

*Read a Minitab Portable Worksheet*

---

## Description

Return a list with the data stored in a file as a Minitab Portable Worksheet.

## Usage

```
read.mtp(file)
```

## Arguments

`file` character variable with the name of the file to read. The file must be in Minitab Portable Worksheet format.

## Value

A list with one component for each column, matrix, or constant stored in the Minitab worksheet.

**Author(s)**

Douglas M. Bates

**References**

<http://www.minitab.com/>

**Examples**

```
## Not run:
read.mtp("ex1-10.mtp")

## End(Not run)
```

---

read.octave

*Read Octave Text Data Files*

---

**Description**

Read a file in Octave text data format into a list.

**Usage**

```
read.octave(file)
```

**Arguments**

`file` a character string with the name of the file to read.

**Details**

This function is used to read in files in Octave text data format, as created by `save -ascii` in Octave. It knows about most of the common types of variables, including the standard atomic (real and complex scalars, matrices, and  $N$ -d arrays, strings, ranges, and boolean scalars and matrices) and recursive (structs, cells, and lists) ones, but has no guarantee to read all types. If a type is not recognized, a warning indicating the unknown type is issued, it is attempted to skip the unknown entry, and NULL is used as its value. Note that this will give incorrect results, and maybe even errors, in the case of unknown recursive data types.

As Octave can read MATLAB binary files, one can make the contents of such files available to R by using Octave's load and save (as text) facilities as an intermediary step.

**Value**

A list with one named component for each variable in the file.

**Author(s)**

Stephen Eglen <[stephen@gnu.org](mailto:stephen@gnu.org)> and Kurt Hornik

**References**

<http://www.octave.org/>

read.spss

*Read an SPSS Data File***Description**

read.spss reads a file stored by the SPSS save or export commands.

**Usage**

```
read.spss(file, use.value.labels = TRUE, to.data.frame = FALSE,
          max.value.labels = Inf, trim.factor.names = FALSE,
          trim_values = TRUE, reencode = NA, use.missings = to.data.frame)
```

**Arguments**

file	Character string: the name of the file or URL to read.
use.value.labels	Convert variables with value labels into R factors with those levels?
to.data.frame	return a data frame?
max.value.labels	Only variables with value labels and at most this many unique values will be converted to factors if use.value.labels = TRUE.
trim.factor.names	Logical: trim trailing spaces from factor levels?
trim_values	logical: should values and value labels have trailing spaces ignored when matching for use.value.labels = TRUE?
reencode	logical: should character strings be re-encoded to the current locale. The default, NA, means to do so in a UTF-8 locale, only. Alternatively character, specifying an encoding to assume.
use.missings	logical: should information on user-defined missing values be used to set the corresponding values to NA?

**Details**

This uses modified code from the PSPP project (<http://www.gnu.org/software/pspp/>) for reading the SPSS formats.

If the filename appears to be a URL (of schemes 'http:', 'ftp:' or 'https:') the URL is first downloaded to a temporary file and then read. ('https:' is only supported on some platforms.)

Occasionally in SPSS value labels will be added to some values of a continuous variable (e.g. to distinguish different types of missing data), and you will not want these variables converted to factors. By setting max.val.labels you can specify that variables with a large number of distinct values are not converted to factors even if they have value labels. In addition, variables will not be converted to factors if there are non-missing values that have no value label. The value labels are then returned in the "value.labels" attribute of the variable.

If SPSS variable labels are present, they are returned as the "variable.labels" attribute of the answer.

Fixed length strings (including value labels) are padded on the right with spaces by SPSS, and so are read that way by R. The default argument trim\_values=TRUE causes trailing spaces to be

ignored when matching to value labels, as examples have been seen where the strings and the value labels had different amounts of padding. See the examples for `sub` for ways to remove trailing spaces in character data.

URL [http://msdn.microsoft.com/en-us/library/ms776446\(VS.85\).aspx](http://msdn.microsoft.com/en-us/library/ms776446(VS.85).aspx) provides a list of translations from Windows codepage numbers to encoding names that `iconv` is likely to know about and so suitable values for `reencode`. Automatic re-encoding is attempted for apparent codepages of 200 or more in a UTF-8 locale: some other high-numbered codepages can be re-encoded on most systems, but the encoding names are platform-dependent (see `iconvlist`).

### Value

A list (or data frame) with one component for each variable in the saved data set.

If what looks like a Windows codepage was recorded in the SPSS file, it is attached (as a number) as attribute `"codepage"` to the result.

There may be attributes `"label.table"` and `"variable.labels"`. Attribute `"label.table"` is a named list of value labels with one element per variable, either `NULL` or a names character vector. Attribute `"variable.labels"` is a named character vector with names the short variable names and elements the long names.

If there are user-defined missing values, there will be a attribute `"Missings"`. This is a named list with one list element per variable. Each element has an element `type`, a length-one character vector giving the type of missingness, and may also have an element `value` with the values corresponding to missingness. This is a complex subject (where the `R` and `C` source code for `read.spss` is the main documentation), but the simplest cases are types `"one"`, `"two"` and `"three"` with a corresponding number of (real or string) values whose labels can be found from the `"label.table"` attribute. Other possibilities are a finite or semi-infinite range, possibly plus a single value. See also [http://www.gnu.org/software/pspp/manual/html\\_node/Missing-Observations.html#Missing-Observations](http://www.gnu.org/software/pspp/manual/html_node/Missing-Observations.html#Missing-Observations).

### Note

If SPSS value labels are converted to factors the underlying numerical codes will not in general be the same as the SPSS numerical values, since the numerical codes in `R` are always 1, 2, 3, ...

You may see warnings about the file encoding for SPSS `save` files: it is possible such files contain non-ASCII character data which need re-encoding. The most common occurrence is Windows codepage 1252, a superset of Latin-1. The encoding is recorded (as an integer) in attribute `"codepage"` of the result if it looks like a Windows codepage. Automatic re-encoding is done only in UTF-8 locales: see argument `reencode`.

### Author(s)

Saikat DebRoy and the R Core team

### Examples

```
## Not run:
read.spss("datafile")
## don't convert value labels to factor levels
read.spss("datafile", use.value.labels = FALSE)
## convert value labels to factors for variables with at most
## ten distinct values.
read.spss("datafile", max.val.labels = 10)

## End(Not run)
```

---

 read.ssd

*Obtain a Data Frame from a SAS Permanent Dataset, via read.xport*

---

### Description

Generates a SAS program to convert the `ssd` contents to SAS transport format and then uses `read.xport` to obtain a data frame.

### Usage

```
read.ssd(libname, sectionnames,
         tmpXport=tempfile(), tmpProgLoc=tempfile(), sascmd="sas")
```

### Arguments

<code>libname</code>	character string defining the SAS library (usually a directory reference)
<code>sectionnames</code>	character vector giving member names. These are files in the <code>libname</code> directory. They will usually have a <code>.ssd0x</code> or <code>.sas7bdat</code> extension, which should be omitted.
<code>tmpXport</code>	character string: location where temporary xport format archive should reside – defaults to a randomly named file in the session temporary directory, which will be removed.
<code>tmpProgLoc</code>	character string: location where temporary conversion SAS program should reside – defaults to a randomly named file in session temporary directory, which will be removed on successful operation.
<code>sascmd</code>	character string giving full path to SAS executable.

### Details

Creates a SAS program and runs it.

Error handling is primitive.

### Value

A data frame if all goes well, or `NULL` with warnings and some enduring side effects (log file for auditing)

### Note

**This requires SAS to be available.** If you have a SAS dataset without access to SAS you will need another product to convert it to a format such as `.csv`, for example ‘Stat/Transfer’ or ‘DBMS/Copy’ or the ‘SAS System Viewer’ (Windows only).

### Author(s)

**Examples**

```
## if there were some files on the web we could get a real
## runnable example
## Not run:
R> list.files("trialdata")
 [1] "baseline.sas7bdat" "form11.sas7bdat" "form12.sas7bdat"
 [4] "form13.sas7bdat" "form22.sas7bdat" "form23.sas7bdat"
 [7] "form3.sas7bdat"   "form4.sas7bdat"   "form48.sas7bdat"
[10] "form50.sas7bdat"  "form51.sas7bdat"  "form71.sas7bdat"
[13] "form72.sas7bdat"  "form8.sas7bdat"   "form9.sas7bdat"
[16] "form90.sas7bdat"  "form91.sas7bdat"

R> baseline <- read.ssd("trialdata","baseline")
R> form90 <- read.ssd("trialdata","form90")

## Or for a Windows example
sashome <- "/Program Files/SAS/SAS 9.1"
read.ssd(file.path(sashome, "core", "sashelp"), "retail",
         sascmd = file.path(sashome, "sas.exe"))

## End(Not run)
```

read.systat

*Obtain a Data Frame from a Systat File***Description**

read.systat reads a rectangular data file stored by the Systat SAVE command as (legacy) \*.sys or more recently \*.syd files.

**Usage**

```
read.systat(file, to.data.frame = TRUE)
```

**Arguments**

file                    character variable with the name of the file to read  
to.data.frame            return a data frame (otherwise a list)

**Details**

The function only reads those Systat files that are rectangular data files (`mtype = 1`), and warns when files have non-standard variable name codings. The files tested were produced on MS-DOS and Windows: files for the Mac version of Systat have a completely different format.

The C code was originally written for an add-on module for Systat described in Bivand (1992 paper). Variable names retain the trailing dollar in the list returned when `to.data.frame` is FALSE, and in that case character variables are returned as is and filled up to 12 characters with blanks on the right. The original function was limited to reading Systat files with up to 256 variables (a Systat limitation); it will now read up to 8192 variables.

If there is a user comment in the header this is returned as attribute "comment". Such comments are always a multiple of 72 characters (with a maximum of 720 chars returned), normally padded with trailing spaces.

**Value**

A data frame (or list) with one component for each variable in the saved data set.

**Author(s)**

Roger Bivand

**References**

Systat Manual, 1987, 1989

Bivand, R. S. (1992) SYSTAT-compatible software for modelling spatial dependence among observations. *Computers and Geosciences* **18**, 951–963.

**Examples**

```
summary(iris)
iris.s <- read.systat(system.file("files/Iris.syd", package="foreign")[1])
str(iris.s)
summary(iris.s)
```

---

read.xport

*Read a SAS XPORT Format Library*

---

**Description**

Reads a file as a SAS XPORT format library and returns a list of data.frames.

**Usage**

```
read.xport(file)
```

**Arguments**

`file` character variable with the name of the file to read. The file must be in SAS XPORT format.

**Value**

If there is a more than one dataset in the XPORT format library, a named list of data frames, otherwise a data frame. The columns of the data frames will be either numeric (corresponding to numeric in SAS) or factor (corresponding to character in SAS). All SAS numeric missing values (including special missing values represented by `._`, `.A` to `.Z` by SAS) are mapped to `R NA`.

Trailing blanks are removed from character columns before conversion to a factor. Some sources claim that character missing values in SAS are represented by `' '` or `" "`: these are not treated as R missing values.

**Author(s)**

Saikat DebRoy <saikat@stat.wisc.edu>

**References**

**Examples**

```
## Not run:
read.xport("transport")

## End(Not run)
```

---

S3 read functions *Read an S3 Binary or data.dump File*

---

**Description**

Reads binary data files or `data.dump` files that were produced in S version 3.

**Usage**

```
data.restore(file, print = FALSE, verbose = FALSE, env = .GlobalEnv)
read.S(file)
```

**Arguments**

<code>file</code>	the filename of the S-PLUS <code>data.dump</code> or binary file.
<code>print</code>	whether to print the name of each object as read from the file.
<code>verbose</code>	whether to print the name of every subitem within each object.
<code>env</code>	environment within which to create the restored object(s).

**Details**

`read.S` can read the binary files produced in some older versions of S-PLUS on either Windows (versions 3.x, 4.x, 2000) or Unix (version 3.x with 4 byte integers). It automatically detects whether the file was produced on a big- or little-endian machine and adapts itself accordingly.

`data.restore` can read a similar range of files produced by `data.dump` and for newer versions of S-PLUS, those from `data.dump(....., oldStyle=TRUE)`.

Not all S3 objects can be handled in the current version. The most frequently encountered exceptions are functions and expressions; you will also have trouble with objects that contain model formulas. In particular, comments will be lost from function bodies, and the argument lists of functions will often be changed.

**Value**

For `read.S`, an R version of the S3 object.

For `data.restore`, the name of the file.

**Author(s)**

Duncan Murdoch

**Examples**

```
## Not run: read.S(file.path("_Data", "myobj"))
data.restore("dumpdata", print = TRUE)

## End(Not run)
```

---

`write.arff`*Write Data into ARFF Files*

---

**Description**

Writes data into Weka Attribute-Relation File Format (ARFF) files.

**Usage**

```
write.arff(x, file, eol = "\n", relation = deparse(substitute(x)))
```

**Arguments**

<code>x</code>	the data to be written, preferably a matrix or data frame. If not, coercion to a data frame is attempted.
<code>file</code>	either a character string naming a file, or a connection. "" indicates output to the standard output connection.
<code>eol</code>	the character(s) to print at the end of each line (row).
<code>relation</code>	The name of the relation to be written in the file.

**Details**

`relation` will be passed through `make.names` before writing to the file, in an attempt to it them acceptable to Weka, and column names what do not start with an alphabetic character will have `X` prepended.

However, the references say that ARFF files are ASCII files, and that encoding is not enforced.

**References**

Attribute-Relation File Format <http://www.cs.waikato.ac.nz/~ml/weka/arff.html>  
[http://weka.sourceforge.net/wekadoc/index.php/en:ARFF\\_\(3.5.1\)](http://weka.sourceforge.net/wekadoc/index.php/en:ARFF_(3.5.1))

[read.arff](#)

**Examples**

```
write.arff(iris, file = "")
```

---

write.dbf	<i>Write a DBF File</i>
-----------	-------------------------

---

### Description

The function tries to write a data frame to a DBF file.

### Usage

```
write.dbf(dataframe, file, factor2char = TRUE, max_nchar = 254)
```

### Arguments

dataframe	a data frame object.
file	a file name to be written to.
factor2char	logical, default TRUE, convert factor columns to character: otherwise they are written as the internal integer codes.
max_nchar	The maximum number of characters allowed in a character field. Strings which exceed this will be truncated with a warning. See Details.

### Details

Dots in column names are replaced by underlines in the DBF file, and names are truncated to 11 characters.

Only vector columns of classes "logical", "numeric", "integer", "character", "factor" and "Date" can be written. Other columns should be converted to one of these.

Maximum precision (number of digits including minus sign and decimal sign) for numeric is 19 - scale (digits after the decimal sign) which is calculated internally based on the number of digits before the decimal sign.

The original DBASE format limited character fields to 254 bytes. It is said that Clipper and FoxPro can read up to 32K, and it is possible to write a reader that could accept up to 65535 bytes. (The documentation suggests that only ASCII characters can be assumed to be supported.) Readers expecting the older standard (which includes Excel 2003, Access 2003 and OpenOffice 2.0) will truncate the field to the maximum width modulo 256, so increase `max_nchar` only if you are sure the intended reader supports wider character fields.

### Value

Invisible NULL.

### Note

Other applications have varying abilities to read the data types used here. Microsoft Access reads "numeric", "integer", "character" and "Date" fields, including recognizing missing values, but not "logical" (read as 0, -1). Microsoft Excel understood all possible types but did not interpret missing values in character fields correctly (showing them as character nuls).

### Author(s)

Nicholas J. Lewin-Koh, modified by Roger Bivand and Brian Ripley; shapelib by Frank Warmerdam.

str(in1)
try2 <- paste(tempfile(), ".dbf", sep = "")
write.dbf(warpbreaks, try2, factor2char = TRUE)
in2 <- read.dbf(try2)
str(in2)
unlink(c(try1, try2))
```

---

write.dta

*Write Files in Stata Binary Format*

---

**Description**

Writes the data frame to file in the Stata binary format. Does not write array variables unless they can be [drop](#)-ed to a vector.

**Usage**

```
write.dta(dataframe, file, version = 7L,
          convert.dates = TRUE, tz = "GMT",
          convert.factors = c("labels", "string", "numeric", "codes"))
```

**Arguments**

dataframe	a data frame.
file	character string giving filename.
version	integer: Stata version: 6, 7, 8 and 10 are supported, and 9 is mapped to 8, 11 to 10.
convert.dates	Convert Date and POSIXt objects to Stata dates?
tz	timezone for date conversion
convert.factors	how to handle factors

## Details

The major differences between file formats in Stata versions is that version 7.0 and later allow 32-character variable names (5 and 6 were restricted to 8-character name). The `abbreviate` function is used to trim long variables to the permitted length. A warning is given if this is needed and it is an error for the abbreviated names not to be unique.

The columns in the data frame become variables in the Stata data set. Missing values are correctly handled.

Unless deselected, R date and date-time objects (`POSIXt` classes) are converted into the Stata format. For date-time objects this may lose information – Stata dates are in days since 1960-1-1. `POSIXct` objects can be written without conversion but will not be understood as dates by Stata; `POSIXlt` objects cannot be written without conversion.

There are four options for handling factors. The default is to use Stata `value labels` for the factor levels. With `convert.factors="string"`, the factor levels are written as strings. With `convert.factors="numeric"` the numeric values of the levels are written, or NA if they cannot be coerced to numeric. Finally, `convert.factors="codes"` writes the underlying integer codes of the factors. This last used to be the only available method and is provided largely for backwards compatibility.

For Stata 8 or later use the default `version=7` – the only advantage of Stata 8 format is that it can represent multiple different missing value types, and R doesn't have them. Stata 10/11 allows longer format lists, but R does not make use of them.

Note that the Stata formats are documented to be use ASCII strings – R does not enforce this, but use of non-ASCII character strings will not be portable as the encoding is not recorded. Up to 244 bytes are allowed in character data, and longer strings will be truncated with a warning.

Stata uses some large numerical values to represent missing values. This function does not currently check, and hence integers greater than 2147483620 and doubles greater than 8.988e+307 may be misinterpreted by Stata.

## Value

NULL

## Examples

```
write.dta(swiss, swissfile <- tempfile())
read.dta(swissfile)
```

---

write.foreign      *Write Text Files and Code to Read Them*

---

### Description

This function exports simple data frames to other statistical packages by writing the data as free-format text and writing a separate file of instructions for the other package to read the data.

### Usage

```
write.foreign(df, datafile, codefile,
              package = c("SPSS", "Stata", "SAS"), ...)
```

### Arguments

df	A data frame
datafile	Name of file for data output
codefile	Name of file for code output
package	Name of package
...	Other arguments for the individual writeForeign functions

### Details

The work for this function is done by `foreign::writeForeignStata`, `foreign::writeForeignSAS` and `foreign::writeForeignSPSS`. To add support for another package, eg Systat, create a function `writeForeignSystat` with the same first three arguments as `write.foreign`. This will be called from `write.foreign` when `package="Systat"`.

Numeric variables and factors are supported for all packages: dates and times (`Date`, `dates`, `date`, and `POSIXt` classes) are also supported for SAS and characters are supported for SPSS.

For `package="SAS"` there are optional arguments `dataname="rdata"` taking a string that will be the SAS data set name and `validvarname` taking either `"V6"` or `"V7"`.

# Chapter 17

## The `lattice` package

---

A\_01\_Lattice

*Lattice Graphics*

---

### Description

Trellis Graphics for R

### Details

Trellis Graphics is a framework for data visualization developed at the Bell Labs by Rick Becker, Bill Cleveland, et al, extending ideas presented in Bill Cleveland's 1993 book *Visualizing Data*. Lattice is an implementation of Trellis Graphics for R.

Type `help(package = lattice)` to see a list of (public) functions for which further documentation is available. The 'See Also' section below lists specific areas of interest with pointers to the help pages with respective details. Apart from the documentation accompanying this package, a book on lattice is also available as part of Springer's 'Use R' series.

Lattice is built upon the Grid graphics engine and requires the `grid` add-on package. It is not (readily) compatible with traditional R graphics tools. The public interface is based on the implementation in S-PLUS, but features several extensions, in addition to incompatibilities introduced through the use of `grid`. To the extent possible, care has been taken to ensure that existing Trellis code written for S-PLUS works unchanged (or with minimal change) in Lattice. If you are having problems porting S-PLUS code, read the entry for `panel` in the documentation for `xypplot`. Most high level Trellis functions in S-PLUS are implemented, with the exception of `piechart`.

The example section below shows how to bring up a brief history of changes to the lattice package, which provides a summary of new features.

### Note

High level Lattice functions (like `xypplot`) are different from conventional R graphics functions because they don't actually draw anything. Instead, they return an object of class "trellis" which has to be then `printed` or `plotted` to create the actual plot. This is normally done automatically, but not when the high level functions are called inside another function (most often `source`) or other contexts where automatic printing is suppressed (e.g. `for` or `while` loops). In such situations, an explicit call to `print` or `plot` is required.

Lattice plots are highly customizable via user-modifiable settings. However, these are completely unrelated to base graphics settings; in particular, changing `par()` settings usually have no effect on lattice plots.

### See Also

The Lattice user interface primarily consists of several ‘high level’ generic functions (listed below), each designed to create a particular type of statistical display by default. While each function does different things, they share several common features, reflected in several common arguments that affect the resulting displays in similar ways. These arguments are extensively (sometimes only) documented in the help page for `xyplot`. This includes a discussion of *conditioning* and control of the Trellis layout.

Lattice employs an extensive system of user-controllable parameters to determine the look and feel of the displays it produces. To learn how to use and customise the Graphical parameters used by the Lattice functions, see `trellis.par.set`. For other settings, see `lattice.options`. The default graphical settings are different for different graphical devices. To learn how to initialise new devices with the desired settings or change the settings of the current device, see `trellis.device`.

To learn about sophisticated (non-default) printing capabilities, see `print.trellis`. See `update.trellis` to learn about manipulating a “trellis” object. Tools to augment lattice plots after they are drawn (including `locator`-like functionality) is described in the `trellis.focus` help page.

The following is a list of ‘high level’ functions in the Lattice package with a brief description of what they do. In all cases, the actual display is produced by the so-called `panel` function, which has a suitable default, but can be substituted by an user defined function to create custom displays. The user will most often be interested in the default panel functions, which have a separate help page, linked to from the help pages of the corresponding high level function. Although documented separately, arguments to these panel functions can be supplied directly to the high level functions, which will forward the arguments as appropriate.

#### Univariate:

`barchart` bar plots

`bwplot` box and whisker plots

`densityplot` kernel density plots

`dotplot` dot plots

[histogram](#) histograms

[qqmath](#) quantile plots against mathematical distributions

[stripplot](#) 1-dimensional scatterplot

**Bivariate:**

[qq](#) q-q plot for comparing two distributions

[xyplot](#) scatter plot (and possibly a lot more)

**Trivariate:**

[levelplot](#) level plots (similar to image plots in R)

[contourplot](#) contour plots

[cloud](#) 3-D scatter plots

[wireframe](#) 3-D surfaces (similar to persp plots in R)

**Hypervariate:**

[splom](#) scatterplot matrix

[parallel](#) parallel coordinate plots

**Miscellaneous:**

[rfs](#) residual and fitted value plot (also see [oneway](#))

[tmd](#) Tukey Mean-Difference plot

Additionally, there are several panel functions that do little by themselves, but can be useful components of custom panel functions. These are documented in [panel.functions](#). Lattice also has a collection of convenience functions that correspond to the base graphics primitives [lines](#), [points](#), etc. They are implemented using Grid graphics, but try to be as close to the base versions as possible in terms of their argument list. These functions have imaginative names like [llines](#) or [panel.lines](#) and are often useful when writing (or porting from S-PLUS code) nontrivial panel functions.

**Examples**

```
## Not run:
RShowDoc("NEWS", package = "lattice")

## End(Not run)
```

**Description**

These are the most commonly used high level Trellis functions to plot pairs of variables. By far the most common is `xyplot`, designed mainly for two continuous variates (though factors can be supplied as well, in which case they will simply be coerced to numeric), which produces Conditional Scatter plots. The others are useful when one of the variates is a factor or a shingle. Most of these arguments are also applicable to other high level functions in the lattice package, but are only documented here.

**Usage**

```

xyplot(x, data, ...)
dotplot(x, data, ...)
barchart(x, data, ...)
stripplot(x, data, ...)
bwplot(x, data, ...)

## S3 method for class 'formula':

subscripts = !is.null(groups),
subset = TRUE)

```

## Arguments

x

The object on which method dispatch is carried out.

For the "formula" methods, a formula describing the form of conditioning plot. The formula is generally of the form  $y \sim x \mid g1 * g2 * \dots$ , indicating that plots of  $y$  (on the  $y$  axis) versus  $x$  (on the  $x$  axis) should be produced conditional on the variables  $g1, g2, \dots$ . However, the conditioning variables  $g1, g2, \dots$  may be omitted. The formula can also be supplied as  $y \sim x \mid g1 + g2 + \dots$ .

For all of these functions, with the exception of `xyplot`, a formula of the form  $\sim x \mid g1 * g2 * \dots$  is also allowed. In that case,  $y$  defaults to `names(x)` if  $x$  is named, and a factor with a single level otherwise.

Other usage of the form `dotplot(x)` is handled by method dispatch as appropriate. The numeric method is equivalent to a call with no left hand side and no conditioning variables in the formula. For `barchart` and `dotplot`, non-trivial methods exist for tables and arrays, documented under [barchart.table](#).

The conditioning variables  $g1, g2, \dots$  must be either factors or shingles. Shingles are a way of processing numeric variables for use in conditioning. See documentation of [shingle](#) for details. Like factors, they have a "levels" attribute, which is used in producing the conditional plots.

Numeric conditioning variables are converted to shingles by the function `shingle` (however, using `equal.count` might be more appropriate in many cases) and character vectors are coerced to factors.

The formula can involve expressions, e.g. `sqrt()`, `log()`.

A special case is when the left and/or right sides of the formula (before the conditioning variables) contain a '+' sign, e.g.,  $y1+y2 \sim x \mid a*b$ . This for-

mula would be taken to mean that the user wants to plot both  $y1 \sim x \mid a*b$  and  $y2 \sim x \mid a*b$ , but with the  $y1 \sim x$  and  $y2 \sim x$  superposed in each panel (this is slightly more complicated in `barchart`). The two parts would be distinguished by different graphical parameters. This is essentially what the `groups` argument would produce, if  $y1$  and  $y2$  were concatenated to produce a longer vector, with the `groups` argument being an indicator of which rows come from which variable. In fact, this is exactly what is done internally using the `reshape` function. This feature cannot be used in conjunction with the `groups` argument.

To interpret  $y1 + y2$  as a sum, one can either set `allow.multiple=FALSE` or use `I(y1+y2)`.

A variation on this feature is when the `outer` argument is set to `TRUE` as well as `allow.multiple`. In that case, the plots are not superposed in each panel, but instead separated into different panels (as if a new conditioning variable had been added).

The `x` and `y` variables should both be numeric in `xyplot`, and an attempt is made to coerce them if not. However, if either is a factor, the levels of that factor are used as axis labels. In the other four functions documented here, exactly one of `x` and `y` should be numeric, and the other a factor or shingle. Which of these will happen is determined by the `horizontal` argument — if `horizontal=TRUE`, then `y` will be coerced to be a factor or shingle, otherwise `x`. The default value of `horizontal` is `FALSE` if `x` is a factor or shingle, `TRUE` otherwise. (The functionality provided by `horizontal=FALSE` is not S-compatible.)

Note that this argument used to be called `formula` in earlier versions (when the high level functions were not generic and the `formula` method was essentially the only method). This is no longer allowed. It is recommended that this argument not be named in any case, but rather be the first (unnamed) argument.

`data` For the `formula` method, a data frame containing values (or more precisely, anything that is a valid `envir` argument in `eval`, e.g. a list or an environment) for any variables in the formula, as well as `groups` and `subset` if applicable. If not found in `data`, or if `data` is unspecified, the variables are looked for in the environment of the formula. For other methods (where `x` is not a formula), `data` is usually ignored, often with a warning.

`allow.multiple, outer` logical flags to control what happens with formulas like  $y1 + y2 \sim x$ . See the entry for `x` for details. `allow.multiple` defaults to `TRUE` whenever it makes sense, and `outer` defaults to `FALSE` except when `groups` is explicitly specified or grouping doesn't make sense for the default panel function

`box.ratio` applicable to `bwplot`, `barchart` and `stripplot`, specifies the ratio of the width of the rectangles to the inter rectangle space.

`horizontal` logical, applicable to `bwplot`, `dotplot`, `barchart` and `stripplot`. Determines which of `x` and `y` is to be a factor or shingle (`y` if `TRUE`, `x` otherwise). Defaults to `FALSE` if `x` is a factor or shingle, `TRUE` otherwise. This argument is used to process the arguments to these high level functions, but more importantly, it is passed as an argument to the panel function, which is supposed to use it as appropriate.

A potentially useful component of `scales` in this case might be `abbreviate = TRUE`, in which case long labels which would usually overlap will be abbreviated. `scales` could also contain a `minlength` argument in this case, which would be passed to the `abbreviate` function.

The following arguments are common to all the functions documented here, as well as most other high level Trellis functions. These are not documented elsewhere, except to override the usage given here.

panel

Once the subset of rows defined by each unique combination of the levels of the grouping variables are obtained (see details), the corresponding  $x$  and  $y$  variables (or other variables, as appropriate, in the case of other high level functions) are passed on to be plotted in each panel. The actual plotting is done by the function specified by the `panel` argument. Each high level function has its own default panel function, which could depend on whether the `groups` argument was supplied.

The panel function can be a function object or a character string giving the name of a predefined function.

Much of the power of Trellis Graphics comes from the ability to define customized panel functions. A panel function appropriate for the functions described here would usually expect arguments named  $x$  and  $y$ , which would be provided by the conditioning process. It can also have other arguments. It might be useful to know in this context that all arguments passed to a high level Trellis function (such as `xyplot`) that are not recognized by it are passed through to the panel function. It is thus generally good practice when defining panel functions to allow a `...` argument. Such extra arguments typically control graphical parameters, but other uses are also common. See documentation for individual panel functions for specifics.

Note that unlike in S-PLUS, it is not guaranteed that panel functions will be supplied only numeric vectors for the  $x$  and  $y$  arguments; they can be factors as well (but not shingles). Panel functions need to handle this case, which in most cases can be done by simply coercing them to numeric.

Technically speaking, panel functions must be written using Grid graphics functions. However, knowledge of Grid is usually not necessary to construct new custom panel functions, there are several predefined panel functions which can help; for example, `panel.grid`, `panel.loess`, etc. There are also some grid-compatible replacements of commonly used base R graphics functions useful for this purpose. For example, `lines` can be replaced by `llines` (or equivalently, `panel.lines`). Note that base R graphics functions like `lines` will not work in a lattice panel function.

One case where a bit more is required of the panel function is when the `groups` argument is not null. In that case, the panel function should also accept arguments named `groups` and `subscripts` (see below for details). A useful panel function predefined for use in such cases is `panel.superpose`, which can be combined with different `panel.groups` functions determining what is plotted for each group. See the examples section for an interaction plot constructed in this way. Several other panel functions can also handle the `groups` argument, including the default ones for `barchart`, `dotplot` and `stripplot`.

Even when `groups` is not present, the panel function can have `subscripts` as a formal argument. In either case, the `subscripts` argument passed to the panel function are the indices of the  $x$  and  $y$  data for that panel in the original data, BEFORE taking into account the effect of the `subset` argument. Note that `groups` remains unaffected by any subsetting operations, so `groups[subscripts]` gives the values of `groups` that correspond to the data in that panel.

This interpretation of `subscripts` does not hold when the extended formula

interface is in use (i.e., when `allow.multiple` is in effect). A comprehensive description would be too complicated (details can be found in the source code of the function `latticeParseFormula`), but in short, the extended interface works by creating an artificial grouping variable that is longer than the original data frame, and consequently, `subscripts` needs to refer to rows beyond those in the original data. To further complicate matters, the artificial grouping variable is created after any effect of `subset`, in which case `subscripts` has practically no relationship with corresponding rows in the original data frame.

One can also use functions called `panel.number` and `packet.number`, representing panel order and packet order respectively, inside the panel function (as well as the strip function or while interacting with a lattice display using `trellis.focus` etc). Both provide a simple integer index indicating which panel is currently being drawn, but differ in how the count is calculated. The panel number is a simple incremental counter that starts with 1 and is incremented each time a panel is drawn. The packet number on the other hand indexes the combination of levels of the conditioning variables that is represented by that panel. The two indices coincide unless the order of conditioning variables is permuted and/or the plotting order of levels within one or more conditioning variables is altered (using `perm.cond` and `index.cond` respectively), in which case `packet.number` gives the index corresponding to the ‘natural’ ordering of that combination of levels of the conditioning variables.

`panel.xyplot` has an argument called `type` which is worth mentioning here because it is quite frequently used (and as mentioned above, can be passed to `xyplot` directly). In the event that a `groups` variable is used, `panel.xyplot` calls `panel.superpose`, arguments of which can also be passed directly to `xyplot`. Panel functions for `bwplot` and friends should have an argument called `horizontal` to account for the cases when `x` is the factor or shingle.

`aspect` controls physical aspect ratio of the panels (same for all the panels). It can be specified as a ratio (vertical size/horizontal size) or as a character string. Legitimate values are `"fill"` (the default) which tries to make the panels as big as possible to fill the available space; `"xy"`, which **tries** to compute the aspect based on the 45 degree banking rule (see *Visualizing Data* by William S. Cleveland for details); and `"iso"` for isometric scales, where the relation between physical distance on the device and distance in the data scale are forced to be the same for both axes.

If a `prepanel` function is specified and it returns components `dx` and `dy`, these are used for banking calculations. Otherwise, values from the default `prepanel` function are used. Currently, only the default `prepanel` function for `xyplot` can be expected to produce sensible banking calculations. See [banking](#) for details on the implementation of banking .

`groups` a variable or expression to be evaluated in the data frame specified by `data`, expected to act as a grouping variable within each panel, typically used to distinguish different groups by varying graphical parameters like color and line type. Formally, if `groups` is specified, then `groups` along with `subscripts` is passed to the panel function, which is expected to handle these arguments. Not all pre-defined panel functions know how to, but for high level functions where grouping is appropriate, the default panel functions are chosen so that they do. It is very common to use a key (legend) when a grouping variable is specified. See entries for `key`, `auto.key` and [simpleKey](#) for how to draw a key.

- `auto.key` A logical, or a list containing components to be used as arguments to `simpleKey`. `auto.key=TRUE` is equivalent to `auto.key=list()`, in which case `simpleKey` is called with a set of default arguments (which may depend on the relevant high-level function). Most valid components to the `key` argument can be specified in this manner, as `simpleKey` will simply add unrecognized arguments to the list it produces.
- `auto.key` is typically used to automatically produce a suitable legend in conjunction with a grouping variable. If `auto.key=TRUE`, a suitable legend will be drawn if a `groups` argument is also provided, and not otherwise. In list form, `auto.key` will modify the default legend thus produced. For example, `auto.key=list(columns = 2)` will create a legend split into two columns (`columns` is documented in the entry for `key`).
- More precisely, if `auto.key` is not `FALSE`, `groups` is non-null, and there is no `key` or `legend` argument specified in the call, a key is created with `simpleKey` with `levels(groups)` as the first (`text`) argument. (Note: this may not work in all high level functions, but it does work for the ones where grouping makes sense with the default panel function). If `auto.key` is provided as a list and includes a `text` component, then that is used instead as the text labels in the key, and the key is drawn even if `groups` is not specified. Note that `simpleKey` uses the default settings (see `trellis.par.get`) to determine the graphical parameters in the key, so the resulting legend will be meaningful only if the same settings are used in the plot as well.
- One disadvantage to using `key` (or even `simpleKey`) directly is that the graphical parameters used in the key are absolutely determined at the time when the "trellis" object is created. Consequently, if a plot once created is re-plotted with different settings, the original parameter settings will be used for the key even though the new settings are used for the actual display. However, with `auto.key`, the key is actually created at plotting time, so the settings will match.
- `prepanel` function that takes the same arguments as the `panel` function and returns a list, possibly containing components named `xlim`, `ylim`, `dx` and `dy` (and less frequently, `xat` and `yat`).
- The `xlim` and `ylim` components are similar to the high level `xlim` and `ylim` arguments (i.e., they are usually a numeric vector of length 2 defining a range of values, or a character vector representing levels of a factor). If the `xlim` and `ylim` arguments are not explicitly specified (possibly as components in `scales`), then the actual limits of the panels are guaranteed to include the limits returned by the `prepanel` function. This happens globally if the `relation` component of `scales` is "same", and on a panel by panel basis otherwise. See `xlim` to see what forms of the components `xlim` and `ylim` are allowed.
- The `dx` and `dy` components are used for banking computations in case `aspect` is specified as "xy". See documentation for the function `banking` for details regarding how this is done.
- The return value of the `prepanel` function need not have all the components named above; in case some are missing, they are replaced by the usual component-wise defaults.
- If `xlim` or `ylim` is a character vector (which is appropriate when the corresponding variable is a factor), this implicitly indicates that the scale should include the first `n` integers, where `n` is the length of `xlim` or `ylim`, as the case may be. The elements of the character vector are used as the default labels for these `n` integers. Thus, to make this information consistent between panels, the

`xlim` or `ylim` values should represent all the levels of the corresponding factor, even if some are not used within that particular panel.

In such cases, an additional component `xat` or `yat` may be returned by the `prepanel` function, which should be a subset of `1:n`, indicating which of the `n` values (levels) are actually represented in the panel. This is useful when calculating the limits with `relation="free"` or `relation="sliced"` in `scales`.

The `prepanel` function is responsible for providing a meaningful return value when the `x`, `y` (etc.) variables are zero-length vectors. When nothing is appropriate, values of `NA` should be returned for the `xlim` and `ylim` components.

<code>strip</code>	logical flag or function. If <code>FALSE</code> , strips are not drawn. Otherwise, strips are drawn using the <code>strip</code> function, which defaults to <code>strip.default</code> . See documentation of <code>strip.default</code> to see the arguments that are available to the <code>strip</code> function. This description also applies to the <code>strip.left</code> argument (see . . . below), which can be used to draw strips on the left of each panel, which can be useful for wide short panels, e.g. in time series plots.
<code>xlab</code>	character string or expression (or a "grob") giving label for the x-axis. Defaults to the expression for <code>x</code> in <code>formula</code> . Can be specified as <code>NULL</code> to omit the label altogether. Finer control is possible, as described in the entry for <code>main</code> , with the additional feature that if the <code>label</code> component is omitted from the list, it is replaced by the default <code>xlab</code> .
<code>ylab</code>	character string or expression (or "grob") giving label for the y-axis. Defaults to the expression for <code>y</code> in <code>formula</code> . Fine control is possible, see entries for <code>main</code> and <code>xlab</code> .
<code>scales</code>	list determining how the x- and y-axes (tick marks and labels) are drawn. The list contains parameters in <code>name=value</code> form, and may also contain two other lists called <code>x</code> and <code>y</code> of the same form (described below). Components of <code>x</code> and <code>y</code> affect the respective axes only, while those in <code>scales</code> affect both. When parameters are specified in both lists, the values in <code>x</code> or <code>y</code> are used. Note that certain high-level functions have defaults that are specific to a particular axis (e.g., <code>bwplot</code> has <code>alternating=FALSE</code> for the y-axis only); these can be overridden only by an entry in the corresponding component of <code>scales</code> .

The possible components are :

`relation` character string that determines how axis limits are calculated for each panel. Possible values are "same" (default), "free" and "sliced". For `relation="same"`, the same limits, usually large enough to encompass all the data, are used for all the panels. For `relation="free"`, limits for each panel is determined by just the points in that panel. Behavior for `relation="sliced"` is similar, except that the length (max - min) of the scales are constrained to remain the same across panels.

The determination of what axis limits are suitable for each panel can be controlled by the `prepanel` function, which can be overridden by `xlim`, `ylim` or `scales$limits`. If `relation` is not "same", the value of `xlim` etc is normally ignored, except when it is a list, in which case it is treated as if its components were the limit values obtained from the `prepanel` calculations for each panel.

`tick.number` Suggested number of ticks (ignored for a factor, shingle or character vector, in which case there is no natural rule for leaving out some of the labels. But see `xlim`).

`draw` logical, defaults to TRUE, whether to draw the axis at all.

`alternating` logical specifying whether axis labels should alternate from one side of the group of panels to the other. For finer control, `alternating` can be a vector (replicated to be as long as the number of rows or columns per page) consisting of the following numbers

- 0: do not draw tick labels
- 1: bottom/left
- 2: top/right
- 3: both.

`alternating` applies only when `relation="same"`. The default is TRUE, or equivalently, `c(1, 2)`

`limits` same as `xlim` and `ylim`.

`at` location of tick marks along the axis (in native coordinates), or a list as long as the number of panels describing tick locations for each panel.

`labels` Labels (strings or expressions) to go along with `at`. Can be a list like `at` as well.

`cex` numeric multiplier to control character sizes for axis labels. Can be a vector of length 2, to control left/bottom and right/top separately.

`font`, `fontface`, `fontfamily` specifies font for axis labels.

`tck` numeric to control length of tick marks. Can be a vector of length 2, to control left/bottom and right/top separately.

`col` color of ticks and labels.

`rot` Angle by which the axis labels are to be rotated. Can be a vector of length 2, to control left/bottom and right/top separately.

`abbreviate` logical, whether to abbreviate the labels using `abbreviate`. Can be useful for long labels (e.g., in factors), especially on the x-axis.

`minlength` argument passed to `abbreviate` if `abbreviate=TRUE`.

`log` Controls whether the corresponding variable (`x` or `y`) will be log transformed before being passed to the panel function. Defaults to FALSE, in which case the data are not transformed. Other possible values are any number that works as a base for taking logarithm, TRUE (which is equivalent to 10), and "e" (for the natural logarithm). As a side effect, the corresponding axis is labeled differently. Note that this is a transformation of the data, not the axes. Other than the axis labeling, using this feature is no different than transforming the data in the formula; e.g., `scales=list(x = list(log = 2))` is equivalent to  $y \sim \log_2(x)$ .

`format` the format to use for POSIXct variables. See `strptime` for description of valid values.

`axs` character, "r" or "i". In the latter case, the axis limits are calculated as the exact data range, instead of being padded on either side. (May not always work as expected.)

Note that much of the function of `scales` is accomplished by `pcales` in `splom`.

`subscripts` logical specifying whether or not a vector named `subscripts` should be passed to the panel function. Defaults to FALSE, unless `groups` is specified, or if the panel function accepts an argument named `subscripts`. (One should be careful when defining the panel function on-the-fly.)

`subset` logical or integer indexing vector (can be specified in terms of variables in data). Only these rows of data will be used for the plot. If `subscripts` is

- TRUE, the subscripts will provide indices to the rows of data before the subsetting is done. Whether levels of factors in the data frame that are unused after the subsetting will be dropped depends on the `drop.unused.levels` argument.
- `xlim` Normally a numeric vector of length 2 (possibly a `DateTime` object) giving minimum and maximum for the x-axis, or, a character vector, expected to denote the levels of `x`. The latter form is interpreted as a range containing `c(1, length(xlim))`, with the character vector determining labels at tick positions `1:length(xlim)`
- `xlim` could also be a list, with as many components as the number of panels (recycled if necessary), with each component as described above. This is meaningful only when `scales$x$relation` is "free" or "sliced", in which case these are treated as if they were the corresponding limit components returned by `prepanel` calculations.
- `ylim` similar to `xlim`, applied to the y-axis.
- `drop.unused.levels` logical indicating whether the unused levels of factors will be dropped, usually relevant with a subsetting operation is performed or an [interaction](#) is created. Unused levels are usually dropped, but it is sometimes appropriate to suppress dropping to preserve a useful layout. For finer control, this argument could also be list containing components `cond` and `data`, both logical, indicating desired behavior for conditioning variables and data variables respectively. The default is given by `lattice.getOption("drop.unused.levels")`, which is initially set to TRUE for both components. Note that this argument does not control dropping of levels of the `groups` argument.
- `default.scales` list giving the default values of `scales` for a particular high level function. This should not be of any interest to the normal user, but may be helpful when defining other functions that act as a wrapper to one of the high level lattice functions.
- `lattice.options` a list that could be supplied to `lattice.options`. These options are temporarily in effect for the duration of the call, after which the settings revert back to whatever they were before. The settings are also retained along with the object and reused during plotting. This enables the user to attach options settings to the trellis object itself rather than change the settings globally. See also the `par.settings` argument described below for a similar treatment of graphical settings.
- ... further arguments, usually not directly processed by the high level functions documented here, but rather passed on to other functions. Such arguments can be broadly categorized into two types: those that affect all high level Trellis functions in a similar manner, and those that are meant for the specific panel function used, which may differ across high level functions.
- The first group of arguments are processed by a common, unexported function called `trellis.skeleton`. These arguments affect all high level functions, but are only documented here, except to override the behaviour described here. All other arguments specified in a high level call, specifically those neither described here nor in the help page of the relevant high level function, are passed unchanged to the panel function used. By convention, the default panel function used for any high level function is named as "panel." followed by the name of the high level function; for example, the default panel function for `bwplot` is `panel.bwplot`. In practical terms, this means that in addition to the help

page of the high level function being used, the user should also consult the help page of the corresponding panel function for arguments that may be specified in the high level call.

The effect of the first group of common arguments are as follows:

`as.table`: logical that controls the order in which panels should be plotted: if `FALSE` (the default), panels are drawn left to right, bottom to top (as in a graph); if `TRUE`, left to right, top to bottom.

`between`: a list with components `x` and `y` (both usually 0 by default), numeric vectors specifying the space between the panels (units are character heights). `x` and `y` are repeated to account for all panels in a page and any extra components are ignored. The result is used for all pages in a multi page display. (In other words, it is not possible to use different `between` values for different pages).

`key`: A list of arguments that define a legend to be drawn on the plot. This list is used as an argument to the `draw.key` function, which produces a grid object eventually plotted by the print method for "trellis" objects.

There is also a less flexible but usually sufficient shortcut function `simpleKey` that can generate such a list, as well as the argument `auto.key` that can be convenient in the most common situation where legends are used, namely when there is a grouping variable. To use more than one legend, or to have arbitrary legends not constrained by the structure imposed by `key`, use the `legend` argument.

The position of the key can be controlled in either of two possible ways. If a component called `space` is present, the key is positioned outside the plot region, in one of the four sides, determined by the value of `space`, which can be one of "top", "bottom", "left" and "right". Alternatively, the key can be positioned inside the plot region by specifying components `x`, `y` and `corner`. `x` and `y` determine the location of the corner of the key given by `corner`, which is usually one of `c(0, 0)`, `c(1, 0)`, `c(1, 1)` and `c(0, 1)`, which denote the corners of the unit square. Fractional values are also allowed, in which case `x` and `y` determine the position of an arbitrary point inside (or outside for values outside the unit interval) the key.

`x` and `y` should be numbers between 0 and 1, giving coordinates with respect to the "display area". Depending on the value of `lattice.getOption("legend.bbox")`, this can be either the full figure region ("full"), or just the region that bounds the panels and strips ("panel").

The key essentially consists of a number of columns, possibly divided into blocks, each containing some rows. The contents of the key are determined by (possibly repeated) components named "rectangles", "lines", "points" or "text". Each of these must be lists with relevant graphical parameters (see later) controlling their appearance. The `key` list itself can contain graphical parameters, these would be used if relevant graphical components are omitted from the other components.

The length (number of rows) of each such column (except "text"s) is taken to be the largest of the lengths of the graphical components, including the ones specified outside (see the entry for `rep` below for details on this). The "text" component has to have a character or expression vector as its first component, and the length of this vector determines the number of rows.

The graphical components that can be included in `key` (and also in the com-

ponents named "text", "lines", "points" and "rectangles" as appropriate) are:

- `cex=1`
- `col="black"`
- `alpha=1`
- `lty=1`
- `lwd=1`
- `font=1`
- `fontface`
- `fontfamily`
- `pch=8`
- `adj=0`
- `type="l"`
- `size=5`
- `angle=0`
- `density=-1`

In addition, the component `border` can be included inside the "rect" component to control the border color of the rectangles; when specified at the top level, `border` controls the border of the entire key (see below).

`angle` and `density` are unimplemented. `size` determines the width of columns of rectangles and lines in character widths. `type` is relevant for lines; "l" denotes a line, "p" denotes a point, and "b" and "o" both denote both together.

Other possible components of `key` are:

`reverse.rows` logical, defaulting to `FALSE`. If `TRUE`, all components are reversed *after* being replicated (the details of which may depend on the value of `rep`). This is useful in certain situations, e.g. with a grouped `barchart` with `stack = FALSE` with the categorical variable on the vertical axis, where the bars in the plot will usually be ordered from bottom to top, but the corresponding legend will have the levels from top to bottom (unless, of course, `reverse.rows = TRUE`). Note that in this case, unless all columns have the same number of rows, they will no longer be aligned.

`between` numeric vector giving the amount of space (character widths) surrounding each column (split equally on both sides)

`title` string or expression giving a title for the key

`rep` logical, defaults to `TRUE`. By default, it's assumed that all columns in the key (except the "text"s) will have the same number of rows, and all components are replicated to be as long as the longest. This can be suppressed by specifying `rep=FALSE`, in which case the length of each column will be determined by components of that column alone.

`cex.title` `cex` for the title

`lines.title` how many lines the title should occupy (in multiples of itself). Defaults to 2.

`padding.text` how much space (padding) should be used above and below each row containing text, in multiples of the default, which is currently  $0.2 * \text{"lines"}$ . This padding is in addition to the normal height of any row that contains text, which is the minimum amount necessary to contain all the text entries.

- `background` background color, defaults to default background
- `alpha.background` An alpha transparency value between 0 and 1
- `border` either a color for the border, or a logical. In the latter case, the border color is black if `border` is TRUE, and no border is drawn if it is FALSE (the default)
- `transparent=FALSE` logical, whether key area should have a transparent background
- `columns` the number of columns column-blocks the key is to be divided into, which are drawn side by side.
- `between.columns` Space between column blocks, in addition to `between`.
- `divide` Number of point symbols to divide each line when `type` is "b" or "o" in lines.
- legend:** the legend argument can be useful if one wants to place more than one key. It also allows one to use arbitrary "grob"s (grid objects) as legends. If used, `legend` must be a list, with an arbitrary number of components. Each component must be named one of "left", "right", "top", "bottom" or "inside". The name "inside" can be repeated, but not the others. This name will be used to determine the location for that component, and is similar to the `space` component of `key`. If `key` (or `colorkey` for `levelplot` and `wireframe`) is specified, their `space` component must not conflict with the name of any component of `legend`. Each component of `legend` must have a component called `fun`. This can be a "grob", or a function or the name of a function that produces a "grob" when called. If this function expects any arguments, they must be supplied as a list in another component called `args`. For components named "inside", there can be additional components called `x`, `y` and `corner`, which work in the same way as it does for `key`.
- page:** a function of one argument (page number) to be called after drawing each page. The function must be 'grid-compliant', and is called with the whole display area as the default viewport.
- main:** typically a character string or expression describing the main title to be placed on top of each page. Defaults to NULL. `main` (as well as `xlab`, `ylab` and `sub`) is usually a character string or an expression that gets used as the label, but can also be a list that controls further details. Expressions are treated as specification of LaTeX-like markup as described in `plotmath`. The label can be a vector, in which case the components will be spaced out horizontally (or vertically for `ylab`). This feature can be used to provide column or row labels rather than a single axis label. When `main` (etc.) is a list, the actual label should be specified as the `label` component (which may be unnamed if it is the first component). The label can be missing, in which case the default will be used (`xlab` and `ylab` usually have defaults, but `main` and `sub` do not). Further named arguments are passed on to `textGrob`; this can include arguments controlling positioning like `just` and `rot` as well as graphical parameters such as `col` and `font` (see `gpar` for a full list). `main`, `xlab`, `ylab` and `sub` can also be an arbitrary "grob" (grid graphical object).
- sub:** character string or expression (or a list or "grob") for a subtitle to be placed at the bottom of each page. See entry for `main` for finer control options.

- `par.strip.text`: list of parameters to control the appearance of strip text. Notable components are `col`, `cex`, `font` and `lines`. The first three control graphical parameters while the last is a means of altering the height of the strips. This can be useful, for example, if the strip labels (derived from factor levels, say) are double height (i.e., contains "`\n`"-s) or if the default height seems too small or too large. The `lineheight` component can control the space between multiple lines. Also, the labels can be abbreviated when shown by specifying `abbreviate = TRUE`, in which case the components `minlength` and `dot` (passed along to the `abbreviate` function) can be specified to control the details of how this is done.
- `layout`: In general, a Trellis conditioning plot consists of several panels arranged in a rectangular array, possibly spanning multiple pages. `layout` determines this arrangement. `layout` is a numeric vector giving the number of columns, rows and pages in a multi panel display. By default, the number of columns is the number of levels of the first conditioning variable and the number of rows is the number of levels of the second conditioning variable. If there is only one conditioning variable, the default layout vector is `c(0, n)`, where `n` is the number of levels of the given vector. Any time the first value in the layout vector is 0, the second value is used as the desired number of panels per page and the actual layout is computed from this, taking into account the aspect ratio of the panels and the device dimensions (via `par("din")`). The number of pages is by default set to as many as is required to plot all the panels. In general, giving a high value of `layout[3]` is not wasteful because blank pages are never created. If `NA` is specified for the number of rows or columns (not both), that dimension will be filled out according to the number of panels.
- `skip`: logical vector (default `FALSE`), replicated to be as long as the number of panels (spanning all pages). For elements that are `TRUE`, the corresponding panel position is skipped; i.e., nothing is plotted in that position. The panel that was supposed to be drawn there is now drawn in the next available panel position, and the positions of all the subsequent panels are bumped up accordingly. This is often useful for arranging plots in an informative manner.
- `strip.left`: `strip.left` can be used to draw strips on the left of each panel, which can be useful for wide short panels, as in time series (or similar) plots. It is a function similar to `strip`.
- `xlab.default`, `ylab.default`: fallback default for `xlab` and `ylab` when they are not specified. If `NULL`, the defaults are parsed from the Trellis formula. This is rarely useful for the end-user, but can be helpful when developing new Trellis functions.
- `xscale.components`, `yscale.components`: functions that determine axis annotation for the x and y axes respectively. See documentation for `xscale.components.default`, the default values of these arguments, to learn more.
- `axis`: function that draws axis annotation. See documentation for `axis.default`, the default value of this argument, to learn more.
- `perm.cond`: numeric vector, a permutation of `1:n`, where `n` is the number of conditioning variables. By default, the order in which panels are drawn depends on the order of the conditioning variables specified in the formula. `perm.cond` can modify this order. If the trellis display is thought of as

an n-dimensional array, then during printing, its dimensions are permuted using `perm.cond` as the `perm` argument to `aperm`.

`index.cond`: While `perm.cond` permutes the dimensions of the multidimensional array of panels, `index.cond` can be used to subset (or reorder) margins of that array. `index.cond` can be a list or a function, with behavior in each case described below.

The panel display order within each conditioning variable depends on the order of their levels. `index.cond` can be used to choose a ‘subset’ (in the R sense) of these levels, which is then used as the display order for that variable. If `index.cond` is a list, it has to be as long as the number of conditioning variables, and the *i*-th component has to be a valid indexing vector for `levels(g_i)`, where `g_i` is the *i*-th conditioning variable in the plot (note that these levels may not contain all levels of the original variable, depending on the effects of the `subset` and `drop.unused.levels` arguments). In particular, this indexing may repeat levels, or drop some altogether. The result of this indexing determines the order of panels within that conditioning variable. To keep the order of a particular variable unchanged, the corresponding component must be set to `TRUE`.

Note that the components of `index.cond` are in the order of the conditioning variables in the original call, and is not affected by `perm.cond`.

Another possibility is to specify `index.cond` as a function. In this case, this function is called once for each panel, potentially with all arguments that are passed to the panel function for that panel. (More specifically, if this function has a `...` argument, then all panel arguments are passed, otherwise, only named arguments that match are passed.) For a single conditioning variable, the levels of that variable are then sorted so that these values are in ascending order. For multiple conditioning variables, the order for each variable is determined by first taking the average over all other conditioning variables.

Although they can be supplied in high level function calls directly, it is more typical to use `perm.cond` and `index.cond` to update an existing "trellis" object, thus allowing it to be displayed in a different arrangement without re-calculating the data subsets that go into each panel. In the `update` method, both can be set to `NULL`, which reverts these back to their defaults.

`par.settings`: a list that could be supplied to `trellis.par.set`. This enables the user to attach some display settings to the trellis object itself rather than change the settings globally. When the object is plotted, these settings are temporarily in effect for the duration of the plot, after which the settings revert back to whatever they were before.

`plot.args`: a list of possible arguments to `plot.trellis`, which will be used by the `plot` or `print` methods when drawing the object, unless overridden explicitly. This enables the user to attach such arguments to the trellis object itself. Partial matching is not performed.

## Details

All the functions documented here are generic, with the `formula` method usually doing the actual work. The structure of the plot that is produced is mostly controlled by the formula. For each unique combination of the levels of the conditioning variables `g1`, `g2`, `...`, a separate panel is produced using the points  $(x, y)$  for the subset of the data (also called packet) defined by that combination. The display can be thought of as a 3-dimensional array of panels, consisting of

one 2-dimensional matrix per page. The dimensions of this array are determined by the `layout` argument. If there are no conditioning variables, the plot produced consists of a single panel.

The coordinate system used by `lattice` by default is like a graph, with the origin at the bottom left, with axes increasing right and up. In particular, panels are by default drawn starting from the bottom left corner, going right and then up; unless `as.table = TRUE`, in which case panels are drawn from the top left corner, going right and then down. One might wish to set a global preference for a table-like arrangement by changing the default to `as.table=TRUE`; this can be done by setting `lattice.options(default.args = list(as.table = TRUE))`. In fact, default values can be set in this manner for the following arguments: `as.table`, `aspect`, `between`, `page`, `main`, `sub`, `par.strip.text`, `layout`, `skip` and `strip`. Note that these global defaults are sometimes overridden by individual functions.

The order of the panels depends on the order in which the conditioning variables are specified, with `g1` varying fastest. Within a conditioning variable, the order depends on the order of the levels (which for factors is usually in alphabetical order). Both of these orders can be modified using the `index.cond` and `perm.cond` arguments, possibly using the `update` (and other related) method(s).

### Value

An object of class `"trellis"`. The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

### Note

Most of the arguments documented here are also applicable for the other high level functions in the `lattice` package. These are not described in any detail elsewhere unless relevant, and this should be considered the canonical documentation for such arguments.

Any arguments passed to these functions and not recognized by them will be passed to the panel function. Most predefined panel functions have arguments that customize its output. These arguments are described only in the help pages for these panel functions, but can usually be supplied as arguments to the high level plot.

---

 B\_01\_xyplot.ts      *Time series plotting methods*

---

### Description

This function handles time series plotting, including cut-and-stack plots. Examples are given of superposing, juxtaposing and styling different time series.

### Usage

```
## S3 method for class 'ts':
xyplot(x, data = NULL,
       screens = if (superpose) 1 else colnames(x),
       ...,
       superpose = FALSE,
       cut = FALSE,
       type = "l",
       col = NULL,
       lty = NULL,
       lwd = NULL,
       pch = NULL,
       cex = NULL,
       fill = NULL,
       auto.key = superpose,
       panel = if (superpose) "panel.superpose"
               else "panel.superpose.plain",
       par.settings = list(),
       layout = NULL, as.table = TRUE,
       xlab = "Time", ylab = NULL,
       default.scales = list(y = list(relation =
                                     if (missing(cut)) "free" else "same")))
```

### Arguments

x	an object of class <code>ts</code> , which may be multi-variate, i.e. have a matrix structure with multiple columns.
data	not used, and must be left as <code>NULL</code> .
...	additional arguments passed to <code>xyplot</code> , which may pass them on to <code>panel.xyplot</code> .
screens	factor (or coerced to factor) whose levels specify which panel each series is to be plotted in. <code>screens = c(1, 2, 1)</code> would plot series 1, 2 and 3 in panels 1, 2 and 1. May also be a named list, see Details below.
superpose	overlays all series in one panel (via <code>screens = 1</code> ) and uses grouped style settings (from <code>trellis.par.get("superpose.line")</code> , etc). Note that this is just a convenience argument: its only action is to change the default values of other arguments.

<code>cut</code>	defines a cut-and-stack plot. <code>cut</code> can be a list of arguments to the function <code>equal.count</code> , i.e. <code>number</code> (number of intervals to divide into) and <code>overlap</code> (the fraction of overlap between cuts, default 0.5). If <code>cut</code> is numeric this is passed as the <code>number</code> argument.  <code>cut = TRUE</code> tries to choose an appropriate number of cuts (up to a maximum of 6), using <code>banking</code> , and assuming a square plot region. This should have the effect of minimising wasted space when <code>aspect = "xy"</code> .
<code>type, col, lty, lwd, pch, cex, fill</code>	graphical arguments, which are processed and eventually passed to <code>panel.xyplot</code> . These arguments can also be vectors or (named) lists, see <code>Details</code> for more information.
<code>auto.key</code>	a logical, or a list describing how to draw a key. See the <code>auto.key</code> entry in <code>xyplot</code> . The default here is to draw lines, not points, and any specified style arguments should show up automatically.
<code>panel</code>	the panel function. It is recommended to leave this alone, but one can pass a <code>panel.groups</code> argument which is handled by <code>panel.superpose</code> for each series.
<code>par.settings</code>	style settings beyond the standard <code>col, lty, lwd, etc</code> ; see <code>trellis.par.set</code> and <code>simpleTheme</code> .
<code>layout</code>	numeric vector of length 2 specifying number of columns and rows in the plot. The default is to fill columns with up to 6 rows.
<code>as.table</code>	to draw panels from top to bottom. The order is determined by the order of columns in <code>x</code> .
<code>xlab, ylab</code>	X axis and Y axis labels; see <code>xyplot</code> . Note in particular that <code>ylab</code> may be a character vector, in which case the labels are spaced out equally, to correspond to the panels; but <i>NOTE</i> in this case the vector should be reversed OR the argument <code>as.table</code> set to <code>FALSE</code> .
<code>default.scales</code>	scales specification. The default is set to have "free" Y axis scales unless <code>cut</code> is given. Note, users should pass the <code>scales</code> argument rather than <code>default.scales</code> .

## Details

The handling of several graphical parameters is more flexible for multivariate series. These parameters can be vectors of the same length as the number of series plotted or are recycled if shorter. They can also be (partially) named list, e.g., `list(A = c(1, 2), c(3, 4))` in which `c(3, 4)` is the default value and `c(1, 2)` the value only for series A. The `screens` argument can be specified in a similar way.

Some examples are given below.

## Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

## Author(s)

Gabor Grothendieck, Achim Zeileis, Deepayan Sarkar and Felix Andrews  
<felix@nfrac.org>.

The first two authors developed `xyplot.ts` in their **zoo** package, including the screens approach. The third author developed a different `xyplot.ts` for cut-and-stack plots in the **lattice-Extra** package. The final author fused these together.

## References

Sarkar, Deepayan (2008) “Lattice: Multivariate Data Visualization with R”, Springer. ISBN: 978-0-387-75968-5 <http://lmdvr.r-forge.r-project.org/> (cut-and-stack plots)

## Examples

```
xyplot(ts(c(1:10,10:1)))

### Figure 14.1 from Sarkar (2008)
xyplot(sunspot.year, aspect = "xy",
       strip = FALSE, strip.left = TRUE,
       cut = list(number = 4, overlap = 0.05))

### A multivariate example; first juxtaposed, then superposed
xyplot(EuStockMarkets, scales = list(y = "same"))
xyplot(EuStockMarkets, superpose = TRUE, aspect = "xy", lwd = 2,
       type = c("l", "g"), ylim = c(0, max(EuStockMarkets)))

### Examples using screens (these two are identical)
xyplot(EuStockMarkets, screens = c(rep("Continental", 3), "UK"))
xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"))

### Automatic group styles
xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"),
       superpose = TRUE)

xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"),
       superpose = TRUE, xlim = extendrange(1996:1998),
       par.settings = standard.theme(color = FALSE))

### Specifying styles for series by name
xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"),
       col = list(DAX = "red", FTSE = "blue", "black"), auto.key = TRUE)

xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"),
       col = list(DAX = "red"), lty = list(SMI = 2), lwd = 1:2,
       auto.key = TRUE)

### Example with simpler data, few data points
set.seed(1)
z <- ts(cbind(a = 1:5, b = 11:15, c = 21:25) + rnorm(5))
xyplot(z, screens = 1)
xyplot(z, screens = list(a = "primary (a)", "other (b & c)"),
       type = list(a = c("p", "h"), b = c("p", "s"), "o"),
       pch = list(a = 2, c = 3), auto.key = list(type = "o"))
```

---

 B\_02\_barchart.table

*table methods for barchart and dotplot*

---

### Description

Contingency tables are often displayed using barcharts and dotplots. These methods are provided for convenience and operate directly on tables. Arrays and matrices are simply coerced to be a table.

### Usage

```
## S3 method for class 'table':
barchart(x, data, groups = TRUE,
         origin = 0, stack = TRUE, ..., horizontal = TRUE)

## S3 method for class 'array':
barchart(x, data, ...)

## S3 method for class 'matrix':
barchart(x, data, ...)

## S3 method for class 'table':
dotplot(x, data, groups = TRUE, ..., horizontal = TRUE)

## S3 method for class 'array':
dotplot(x, data, ...)

## S3 method for class 'matrix':
dotplot(x, data, ...)
```

### Arguments

x	a table, array or matrix object.
data	should not be specified. If specified, will be ignored with a warning.
groups	logical, whether to use the last dimension as the grouping variable in the display.
origin, stack	arguments to <code>panel.barchart</code> controlling the display. The defaults for the table method are different.
horizontal	logical, indicating whether the plot should be horizontal (with the categorical variable on the y-axis) or vertical.
...	other arguments, passed to the underlying <code>formula</code> method.

### Details

The first dimension is used as the variable on the vertical axis. The last dimension is optionally used as a grouping variable (to produce stacked barcharts by default). All other dimensions are used as conditioning variables. The order of these variables cannot be altered (except by permuting the original argument using `t` or `aperm`). For more flexibility, use the `formula` method after converting the table to a data frame using the relevant `as.data.frame` method.

**Value**

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

         auto.key = list(title = "Survived"))
```

---

B\_03\_histogram

*Histograms and Kernel Density Plots*

---

**Description**

Draw Histograms and Kernel Density Plots, possibly conditioned on other variables.

**Usage**

```
histogram(x, data, ...)
densityplot(x, data, ...)
## S3 method for class 'formula':
histogram(x,
          data,
          allow.multiple, outer = TRUE,
          auto.key = FALSE,
          aspect = "fill",
          panel = lattice.getOption("panel.histogram"),
          prepanel, scales, strip, groups,
          xlab, xlim, ylab, ylim,
          type = c("percent", "count", "density"),
          nint = if (is.factor(x)) nlevels(x)
                  else round(log2(length(x)) + 1),
          endpoints = extend.limits(range(as.numeric(x), finite = TRUE), prop =
          breaks,
          equal.widths = TRUE,
          drop.unused.levels = lattice.getOption("drop.unused.levels"),
          ...,
          lattice.options = NULL,
          default.scales = list(),
          subscripts,
          subset)
```

```

## S3 method for class 'numeric':
histogram(x, data = NULL, xlab, ...)
## S3 method for class 'factor':
histogram(x, data = NULL, xlab, ...)

## S3 method for class 'formula':
densityplot(x,
            data,
            allow.multiple = is.null(groups) || outer,
            outer = !is.null(groups),
            auto.key = FALSE,
            aspect = "fill",
            panel = lattice.getOption("panel.densityplot"),
            prepanel, scales, strip, groups, weights,
            xlab, xlim, ylab, ylim,
            bw, adjust, kernel, window, width, give.Rkern,
            n = 50, from, to, cut, na.rm,
            drop.unused.levels = lattice.getOption("drop.unused.levels"),
            ...,
            lattice.options = NULL,
            default.scales = list(),
            subscripts,
            subset)
## S3 method for class 'numeric':
densityplot(x, data = NULL, xlab, ...)

do.breaks(endpoints, nint)

```

## Arguments

<code>x</code>	<p>The object on which method dispatch is carried out.</p> <p>For the <code>formula</code> method, a formula of the form <code>~ x   g1 * g2 * ...</code> indicates that histograms or Kernel Density estimates of <code>x</code> should be produced conditioned on the levels of the (optional) variables <code>g1</code>, <code>g2</code>, <code>...</code>. <code>x</code> can be numeric (or factor for histogram), and each of <code>g1</code>, <code>g2</code>, <code>...</code> must be either factors or shingles.</p> <p>As a special case, the right hand side of the formula can contain more than one variable separated by a <code>+</code> sign. What happens in this case is described in details in the documentation for <a href="#">xyplot</a>. Note that in either form, all the variables involved in the formula have to have same length.</p> <p>For the <code>numeric</code> and <code>factor</code> methods, <code>x</code> replaces the <code>x</code> vector described above. Conditioning is not allowed in these cases.</p>
<code>data</code>	<p>For the <code>formula</code> method, an optional data frame in which variables are to be evaluated. Ignored with a warning in other cases.</p>
<code>type</code>	<p>Character string indicating type of histogram to be drawn. <code>"percent"</code> and <code>"count"</code> give relative frequency and frequency histograms, and can be misleading when breakpoints are not equally spaced. <code>"density"</code> produces a density scale histogram.</p> <p><code>type</code> defaults to <code>"percent"</code>, except when the breakpoints are unequally spaced or <code>breaks = NULL</code>, when it defaults to <code>"density"</code>.</p>

nint	Number of bins. Applies only when <code>breaks</code> is unspecified or <code>NULL</code> in the call. Not applicable when the variable being plotted is a factor.
endpoints	vector of length 2 indicating the range of x-values that is to be covered by the histogram. This applies only when <code>breaks</code> is unspecified and the variable being plotted is not a factor. In <code>do.breaks</code> , this specifies the interval that is to be divided up.
breaks	usually a numeric vector of length (number of bins + 1) defining the breakpoints of the bins. Note that when breakpoints are not equally spaced, the only value of type that makes sense is density. When unspecified, the default is to use <pre>breaks = seq_len(1 + nlevels(x)) - 0.5</pre> <p>when <code>x</code> is a factor, and</p> <pre>breaks = do.breaks(endpoints, nint)</pre> <p>otherwise. Breakpoints calculated in such a manner are used in all panels. Other values of <code>breaks</code> are possible, in which case they affect the display in each panel differently. A special value of <code>breaks</code> is <code>NULL</code>, in which case the number of bins is determined by <code>nint</code> and then breakpoints are chosen according to the value of <code>equal.widths</code>. Other valid values of <code>breaks</code> are those of the <code>breaks</code> argument in <code>hist</code>. This allows specification of <code>breaks</code> as an integer giving the number of bins (similar to <code>nint</code>), as a character string denoting a method, and as a function.</p>
equal.widths	logical, relevant only when <code>breaks=NULL</code> . If <code>TRUE</code> , equally spaced bins will be selected, otherwise, approximately equal area bins will be selected (this would mean that the breakpoints will <b>not</b> be equally spaced).
n	number of points at which density is to be evaluated
panel	The function that uses the packet (subset of display variables) corresponding to a panel to create a display. Default panel functions are documented separately, and often have arguments that can be used to customize its display in various ways. Such arguments can usually be directly supplied to the high level function.
allow.multiple, outer, auto.key, aspect, prepanel, scales, strip, groups, xlab,	See <a href="#">xyplot</a>
weights	numeric vector of weights for the density calculations, evaluated in the non-standard manner used for <code>groups</code> and terms in the formula, if any. If this is specified, it is subsetted using <code>subscripts</code> inside the panel function to match it to the corresponding <code>x</code> values. At the time of writing, <code>weights</code> do not work in conjunction with an extended formula specification (this is not too hard to fix, so just bug the maintainer if you need this feature).
bw, adjust, kernel, window, width, give.Rkern, from, to, cut, na.rm	arguments to <code>density</code> , passed on as appropriate
...	Further arguments. See corresponding entry in <a href="#">xyplot</a> for non-trivial details.

### Details

`histogram` draws Conditional Histograms, while `densityplot` draws Conditional Kernel Density Plots. The density estimate in `densityplot` is actually calculated using the function `density`, and all arguments accepted by it can be passed (as `...`) in the call to `densityplot`

to control the output. See documentation of `density` for details. (Note: The default value of the argument `n` of `density` is changed to 50.)

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

`do.breaks` is an utility function that calculates breakpoints given an interval and the number of pieces to break it into.

### Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

### Note

The form of the arguments accepted by the default panel function `panel.histogram` is different from that in S-PLUS. Whereas S-PLUS calculates the heights inside `histogram` and passes only the breakpoints and the heights to the panel function, here the original variable `x` is passed along with the breakpoints. This allows plots as in the second example below.

### Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

### References

Sarkar, Deepayan (2008) "Lattice: Multivariate Data Visualization with R", Springer. <http://lmdvr.r-forge.r-project.org/>

### Examples

```
require(stats)
histogram( ~ height | voice.part, data = singer, nint = 17,
           endpoints = c(59.5, 76.5), layout = c(2,4), aspect = 1,
           xlab = "Height (inches)")

histogram( ~ height | voice.part, data = singer,
           xlab = "Height (inches)", type = "density",
           panel = function(x, ...) {
             panel.histogram(x, ...)
             panel.mathdensity(dmath = dnorm, col = "black",
                               args = list(mean=mean(x), sd=sd(x)))
           } )

densityplot( ~ height | voice.part, data = singer, layout = c(2, 4),
             xlab = "Height (inches)", bw = 5)
```

**Description**

Quantile-Quantile plot of a sample and a theoretical distribution

**Usage**

```
qqmath(x, data, ...)

## S3 method for class 'formula':
qqmath(x,
       data,
       allow.multiple = is.null(groups) || outer,
       outer = !is.null(groups),
       distribution = qnorm,
       f.value = NULL,
       auto.key = FALSE,
       aspect = "fill",
       panel = lattice.getOption("panel.qqmath"),
       prepanel = NULL,
       scales, strip, groups,
       xlab, xlim, ylab, ylim,
       drop.unused.levels = lattice.getOption("drop.unused.levels"),
       ...,
       lattice.options = NULL,
       default.scales = list(),
       subscripts,
       subset)
## S3 method for class 'numeric':
qqmath(x, data = NULL, ylab, ...)
```

**Arguments**

<code>x</code>	The object on which method dispatch is carried out. For the "formula" method, a formula of the form $\sim x \mid g1 * g2 * \dots$ , where <code>x</code> must be a numeric. For the "numeric" method, a numeric vector.
<code>data</code>	For the <code>formula</code> method, an optional data frame in which variables in the formula (as well as <code>groups</code> and <code>subset</code> , if any) are to be evaluated. Usually ignored with a warning in other methods.
<code>distribution</code>	a quantile function that takes a vector of probabilities as argument and produces the corresponding quantiles. Possible values are <code>qnorm</code> , <code>qunif</code> etc. Distributions with other required arguments need to be passed in as user defined functions.
<code>f.value</code>	optional numeric vector of probabilities, quantiles corresponding to which should be plotted. Can also be a function of a single integer (representing sample size) that returns such a numeric vector. The typical value for this argument is the function <code>ppoints</code> , which is also the S-PLUS default. If specified, the

probabilities generated by this function is used for the plotted quantiles, using the `quantile` function for the sample, and the function specified as the `distribution` argument for the theoretical distribution.

`f.value` defaults to `NULL`, which has the effect of using `ppoints` for the quantiles of the theoretical distribution, but the exact data values for the sample. This is similar to what happens for `qqnorm`, but different from the S-PLUS default of `f.value=ppoints`.

For large `x`, this argument can be useful in plotting a smaller set of quantiles, which is usually enough to capture the pattern.

`panel` The panel function to be used. Unlike in older versions, the default panel function does most of the actual computations and has support for grouping. See [panel.qqmath](#) for details.

`allow.multiple`, `outer`, `auto.key`, `aspect`, `prepanel`, `scales`, `strip`, `groups`, `xlab`,  
See [xyplot](#)

`...` Further arguments. See corresponding entry in [xyplot](#) for non-trivial details.

### Details

`qqmath` produces a Q-Q plot of the given sample and a theoretical distribution. The default behaviour of `qqmath` is different from the corresponding S-PLUS function, but is similar to `qqnorm`. See the entry for `f.value` for specifics.

The implementation details are also different from S-PLUS. In particular, all the important calculations are done by the `panel` (and `prepanel` function) and not `qqmath` itself. In fact, both the arguments `distribution` and `f.value` are passed unchanged to the `panel` and `prepanel` function. This allows, among other things, display of grouped Q-Q plots, which are often useful. See the help page for [panel.qqmath](#) for further details.

This and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

### Value

An object of class `"trellis"`. The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

       panel = function(x, ...) {
         panel.qqmathline(x, ...)
         panel.qqmath(x, ...)
       })

```

B\_05\_qq

*Quantile-Quantile Plots of Two Samples***Description**

Quantile-Quantile plots for comparing two Distributions

**Usage**

```

qq(x, data, ...)

## S3 method for class 'formula':
qq(x, data, aspect = "fill",
   panel = lattice.getOption("panel.qq"),
   prepanel, scales, strip,
   groups, xlab, xlim, ylab, ylim, f.value = NULL,
   drop.unused.levels = lattice.getOption("drop.unused.levels"),
   ...,
   lattice.options = NULL,
   qtype = 7,
   default.scales = list(),
   subscripts,
   subset)

```

**Arguments**

- |      |   |
|------|---|
| x    | The object on which method dispatch is carried out.<br>For the formula method, a formula of the form $y \sim x \mid g_1 * g_2 * \dots$ , where $x$ must be a numeric, and $y$ can be a factor, shingle, character or numeric vector, with the restriction that there must be exactly two levels of $y$ , which divide the values of $x$ into two groups. Quantiles for these groups will be plotted along the two axes. |
| data | For the formula methods, an optional data frame in which variables in the formula (as well as groups and subset, if any) are to be evaluated.   |

<code>f.value</code>	optional numeric vector of probabilities, quantiles corresponding to which should be plotted. Can also be a function of a single integer (representing sample size) that returns such a numeric vector. The typical value for this argument is the function <code>ppoints</code> , which is also the S-PLUS default. If specified, the probabilities generated by this function is used for the plotted quantiles, using the <code>quantile</code> function.  <code>f.value</code> defaults to <code>NULL</code> , which is equivalent to using <code>function(n) ppoints(n, a = 1)</code> . This has the effect of including the minimum and maximum data values in the computed quantiles. This is similar to what happens for <code>qqplot</code> but different from the default <code>qq</code> behaviour in S-PLUS.  For large data, this argument can be useful in plotting a smaller set of quantiles, which is usually enough to capture the pattern.
<code>panel</code>	The function that uses the packet (subset of display variables) corresponding to a panel to create a display. Default panel functions are documented separately, and often have arguments that can be used to customize its display in various ways. Such arguments can usually be directly supplied to the high level function.
<code>qtype</code>	type argument for the <a href="#">quantile</a>
<code>aspect, prepanel, scales, strip, groups, xlab, xlim, ylab, ylim, drop.unused.levels</code>	See <a href="#">xyplot</a>
<code>...</code>	Further arguments. See corresponding entry in <a href="#">xyplot</a> for non-trivial details.

### Details

`qq` produces a Q-Q plot of two samples. The default behaviour of `qq` is different from the corresponding S-PLUS function. See the entry for `f.value` for specifics.

This and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

### Value

An object of class `"trellis"`. The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

            column.values = seq_len(ncol(x)))

## S3 method for class 'array':
levelplot(x, data = NULL, ...)

## S3 method for class 'array':
contourplot(x, data = NULL, ...)

```

## Arguments

- x** for the `formula` method, a formula of the form  $z \sim x * y | g1 * g2 * \dots$ , where  $z$  is a numeric response, and  $x, y$  are numeric values evaluated on a rectangular grid.  $g1, g2, \dots$  are optional conditional variables, and must be either factors or shingles if present. Calculations are based on the assumption that all  $x$  and  $y$  values are evaluated on a grid (defined by their unique values). The function will not return an error if this is not true, but the display might not be meaningful. However, the  $x$  and  $y$  values need not be equally spaced. Both `levelplot` and `wireframe` have methods for `matrix`, `array`, and `table` objects, in which case  $x$  provides the  $z$  vector described above, while its rows and columns are interpreted as the  $x$  and  $y$  vectors respectively. This is similar to the form used in `filled.contour` and `image`. For higher-dimensional arrays and tables, further dimensions are used as conditioning variables. Note that the `dimnames` may be duplicated; this is handled by calling `make.unique` to make the names unique (although the original labels are used for the  $x$ - and  $y$ -axes).
- data** For the `formula` methods, an optional data frame in which variables in the formula (as well as `groups` and `subset`, if any) are to be evaluated. Usually ignored with a warning in other cases.
- row.values, column.values** Optional vectors of values that define the grid when  $x$  is a matrix. `row.values` and `column.values` must have the same lengths as `nrow(x)` and `ncol(x)` respectively. By default, row and column numbers.

panel	panel function used to create the display, as described in <a href="#">xyplot</a>
aspect	For the <code>matrix</code> methods, the default aspect ratio is chosen to make each cell square. The usual default is <code>aspect="fill"</code> , as described in <a href="#">xyplot</a> .
at	numeric vector giving breakpoints along the range of <code>z</code> . Contours (if any) will be drawn at these heights, and the regions in between would be colored using <code>col.regions</code> . In the latter case, values outside the range of <code>at</code> will not be drawn at all. This serves as a way to limit the range of the data shown, similar to what a <code>zlim</code> argument might have been used for. However, this also means that when supplying <code>at</code> explicitly, one has to be careful to include values outside the range of <code>z</code> to ensure that all the data are shown.
col.regions	color vector to be used if <code>regions</code> is <code>TRUE</code> . The general idea is that this should be a color vector of moderately large length (longer than the number of regions. By default this is 100). It is expected that this vector would be gradually varying in color (so that nearby colors would be similar). When the colors are actually chosen, they are chosen to be equally spaced along this vector. When there are more regions than colors in <code>col.regions</code> , the colors are recycled. The actual color assignment is performed by <code>level.colors</code> , which is documented separately.
alpha.regions	numeric, specifying alpha transparency (works only on some devices)
colorkey	logical specifying whether a color key is to be drawn alongside the plot, or a list describing the color key. The list may contain the following components: <code>space</code> : location of the colorkey, can be one of "left", "right", "top" and "bottom". Defaults to "right". <code>x, y</code> : location, currently unused <code>col</code> : vector of colors <code>at</code> : numeric vector specifying where the colors change. must be of length 1 more than the <code>col</code> vector. <code>labels</code> : a character vector for labelling the <code>at</code> values, or more commonly, a list describing characteristics of the labels. This list may include components <code>labels</code> , <code>at</code> , <code>cex</code> , <code>col</code> , <code>rot</code> , <code>font</code> , <code>fontface</code> and <code>fontfamily</code> . <code>tick.number</code> : approximate number of ticks. <code>corner</code> : interacts with <code>x, y</code> ; unimplemented <code>width</code> : width of the key <code>height</code> : length of key w.r.t side of plot.
contour	logical, whether to draw contour lines.
cuts	number of levels the range of <code>z</code> would be divided into
labels	typically a logical indicating whether contour lines should be labelled, but other possibilities for more sophisticated control exists. Details are documented in the help page for <a href="#">panel.levelplot</a> , to which this argument is passed on unchanged. That help page also documents the <code>label.style</code> argument, which affects how the labels are rendered.
pretty	logical, whether to use pretty cut locations and labels
region	logical, whether regions between contour lines should be filled
allow.multiple, outer, prepanel, scales, strip, groups, xlab, xlim, ylab, ylim,	these arguments are described in the help page for <a href="#">xyplot</a> .
...	other arguments. Some are processed by <code>levelplot</code> or <code>contourplot</code> , and those unrecognized are passed on to the panel function.

## Details

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

Other useful arguments are mentioned in the help page for the default panel function `panel.levelplot` (these are formally arguments to the panel function, but can be specified in the high level calls directly).

## Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

      zlab = deparse(substitute(x)), aspect, ...,
      xlim, ylim, row.values, column.values)

## S3 method for class 'table':
cloud(x, data = NULL, groups = FALSE,
      zlab = deparse(substitute(x)),
      type = "h", ...)

## S3 method for class 'matrix':
wireframe(x, data = NULL,
          zlab = deparse(substitute(x)), aspect, ...,
          xlim, ylim, row.values, column.values)

```

## Arguments

**x** The object on which method dispatch is carried out. For the "formula" methods, a formula of the form  $z \sim x * y | g1 * g2 * \dots$ , where  $z$  is a numeric response, and  $x, y$  are numeric values.  $g1, g2, \dots$ , if present, are conditioning variables used for conditioning, and must be either factors or shingles. In the case of `wireframe`, calculations are based on the assumption that the  $x$  and  $y$  values are evaluated on a rectangular grid defined by their unique values. The grid points need not be equally spaced. For `wireframe`,  $x, y$  and  $z$  may also be matrices (of the same dimension), in which case they are taken to represent a 3-D surface parametrized on a 2-D grid (e.g., a sphere). Conditioning is not possible with this feature. See details below. Missing values are allowed, either as NA values in the  $z$  vector, or missing rows in the data frame (note however that in that case the X and Y grids will be determined only by the available values). For a grouped display (producing multiple surfaces), missing rows are not allowed, but NA-s in  $z$  are. Both `wireframe` and `cloud` have methods for `matrix` objects, in which case  $x$  provides the  $z$  vector described above, while its rows and columns are interpreted as the  $x$  and  $y$  vectors respectively. This is similar to the form used in `persp`.

**data** for the "formula" methods, an optional data frame in which variables in the formula (as well as `groups` and `subset`, if any) are to be evaluated. `data` should not be specified except when using the "formula" method.

**row.values, column.values** Optional vectors of values that define the grid when  $x$  is a matrix. `row.values` and `column.values` must have the same lengths as `nrow(x)` and `ncol(x)` respectively. By default, row and column numbers.

**allow.multiple, outer, auto.key, prepanel, strip, groups, xlab, xlim, ylab, ylim** These arguments are documented in the help page for `xyplot`. For the

	<code>cloud.table</code> method, <code>groups</code> must be a logical indicating whether the last dimension should be used as a grouping variable as opposed to a conditioning variable. This is only relevant if the table has more than 2 dimensions.
<code>type</code>	type of display in <code>cloud</code> (see <a href="#">panel.3dscatter</a> for details). Defaults to "h" for the <code>matrix</code> method.
<code>aspect, panel.aspect</code>	unlike other high level functions, <code>aspect</code> is taken to be a numeric vector of length 2, giving the relative aspects of the y-size/x-size and z-size/x-size of the enclosing cube. The usual role of the <code>aspect</code> argument in determining the aspect ratio of the panel (see <a href="#">xyplot</a> for details) is played by <code>panel.aspect</code> , except that it can only be a numeric value. For the <code>matrix</code> methods, the default y/x aspect is <code>ncol(x) / nrow(x)</code> and the z/x aspect is the smaller of the y/x aspect and 1.
<code>panel</code>	panel function used to create the display. See <a href="#">panel.cloud</a> for (non-trivial) details.
<code>scales</code>	a list describing the scales. As with other high level functions (see <a href="#">xyplot</a> for details), this list can contain parameters in <code>name=value</code> form. It can also contain components with the special names <code>x</code> , <code>y</code> and <code>z</code> , which can be similar lists with axis-specific values overriding the ones specified in <code>scales</code> . The most common use for this argument is to set <code>arrows=FALSE</code> , which causes tick marks and labels to be used instead of arrows being drawn (the default). Both can be suppressed by <code>draw=FALSE</code> . Another special component is <code>distance</code> , which specifies the relative distance of the axis label from the bounding box. If specified as a component of <code>scales</code> (as opposed to one of <code>scales\$z</code> etc), this can be (and is recycled if not) a vector of length 3, specifying distances for the x, y and z labels respectively. Other components that work in the <code>scales</code> argument of <code>xyplot</code> etc. should also work here (as long as they make sense), including explicit specification of tick mark locations and labels. (Not everything is implemented yet, but if you find something that should work but does not, feel free to bug the maintainer.) Note, however, that for these functions <code>scales</code> cannot contain information that is specific to particular panels. If you really need that, consider using the <code>scales.3d</code> argument of <code>panel.cloud</code> .
<code>axs.default</code>	Unlike 2-D display functions, <code>cloud</code> does not expand the bounding box to slightly beyond the range of the data, even though it should. This is primarily because this is the natural behaviour in <code>wireframe</code> , which uses the same code. <code>axs.default</code> is intended to provide a different default for <code>cloud</code> . However, this feature has not yet been implemented.
<code>zlab</code>	Specifies a label describing the z variable in ways similar to <code>xlab</code> and <code>ylab</code> (i.e. "grob", character string, expression or list) in other high level functions. Additionally, if <code>zlab</code> (and <code>xlab</code> and <code>ylab</code> ) is a list, it can contain a component called <code>rot</code> , controlling the rotation for the label
<code>zlim</code>	limits for the z-axis. Similar to <code>xlim</code> and <code>ylim</code> in other high level functions
<code>drape</code>	logical, whether the wireframe is to be draped in color. If <code>TRUE</code> , the height of a facet is used to determine its color in a manner similar to the coloring scheme used in <a href="#">levelplot</a> . Otherwise, the background color is used to color the facets. This argument is ignored if <code>shade = TRUE</code> (see <a href="#">panel.3dwire</a> ).
<code>at, col.regions, alpha.regions</code>	these arguments are analogous to those in <a href="#">levelplot</a> . if <code>drape=TRUE</code> , <code>at</code> gives the vector of cutpoints where the colors change, and <code>col.regions</code>

the vector of colors to be used in that case. `alpha.regions` determines the alpha-transparency on supporting devices. These are passed down to the panel function, and also used in the colorkey if appropriate. The default for `col.regions` and `alpha.regions` is derived from the Trellis setting "regions"

`cuts` if `at` is unspecified, the approximate number of cutpoints if `drape=TRUE`

`pretty` whether automatic choice of cutpoints should be prettified

`colorkey` logical indicating whether a color key should be drawn alongside, or a list describing such a key. See [levelplot](#) for details.

... Any number of other arguments can be specified, and are passed to the panel function. In particular, the arguments `distance`, `perspective`, `screen` and `R.mat` are very important in determining the 3-D display. The argument `shade` can be useful for `wireframe` calls, and controls shading of the rendered surface. These arguments are described in detail in the help page for [panel.cloud](#).

Additionally, an argument called `zoom` may be specified, which should be a numeric scalar to be interpreted as a scale factor by which the projection is magnified. This can be useful to get the variable names into the plot. This argument is actually only used by the default `prepanel` function.

## Details

These functions produce three dimensional plots in each panel (as long as the default panel functions are used). The orientation is obtained as follows: the data are scaled to fall within a bounding box that is contained in the  $[-0.5, 0.5]$  cube (even smaller for non-default values of `aspect`). The viewing direction is given by a sequence of rotations specified by the `screen` argument, starting from the positive Z-axis. The viewing point (camera) is located at a distance of  $1/\text{distance}$  from the origin. If `perspective=FALSE`, `distance` is set to 0 (i.e., the viewing point is at an infinite distance).

`cloud` draws a 3-D Scatter Plot, while `wireframe` draws a 3-D surface (usually evaluated on a grid). Multiple surfaces can be drawn by `wireframe` using the `groups` argument (although this is of limited use because the display is incorrect when the surfaces intersect). Specifying `groups` with `cloud` results in a `panel.superpose`-like effect (via [panel.3dscatter](#)).

`wireframe` can optionally render the surface as being illuminated by a light source (no shadows though). Details can be found in the help page for [panel.3dwire](#). Note that although arguments controlling these are actually arguments for the panel function, they can be supplied to `cloud` and `wireframe` directly.

For single panel plots, `wireframe` can also plot parametrized 3-D surfaces (i.e., functions of the form  $f(u,v) = (x(u,v), y(u,v), z(u,v))$ , where values of  $(u,v)$  lie on a rectangle. The simplest example of this sort of surface is a sphere parametrized by latitude and longitude. This can be achieved by calling `wireframe` with a formula `x` of the form  $z \sim x * y$ , where `x`, `y` and `z` are all matrices of the same dimension, representing the values of  $x(u,v)$ ,  $y(u,v)$  and  $z(u,v)$  evaluated on a discrete rectangular grid (the actual values of  $(u,v)$  are irrelevant).

When this feature is used, the heights used to calculate `drape` colors or shading colors are no longer the `z` values, but the distances of  $(x, y, z)$  from the origin.

Note that this feature does not work with `groups`, `subscripts`, `subset`, etc. Conditioning variables are also not supported in this case.

The algorithm for identifying which edges of the bounding box are 'behind' the points doesn't work in some extreme situations. Also, [panel.cloud](#) tries to figure out the optimal location of

the arrows and axis labels automatically, but can fail on occasion (especially when the view is from 'below' the data). This can be manually controlled by the `scpos` argument in `panel.cloud`.

These and all other high level Trellis functions have several other arguments in common. These are extensively documented only in the help page for `xypplot`, which should be consulted to learn more detailed usage.

### Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

### Note

There is a known problem with grouped `wireframe` displays when the (x, y) coordinates represented in the data do not represent the full evaluation grid. The problem occurs whether the grouping is specified through the `groups` argument or through the formula interface, and currently causes memory access violations. Depending on the circumstances, this is manifested either as a meaningless plot or a crash. To work around the problem, it should be enough to have a row in the data frame for each grid point, with an NA response (z) in rows that were previously missing.

```

### Arguments

- |      |  |
|------|--|
| x    | The object on which method dispatch is carried out.<br>For the "formula" method, a formula describing the structure of the plot, which should be of the form $\sim x \mid g1 * g2 * \dots$ , where $x$ is a data frame or matrix. Each of $g1, g2, \dots$ must be either factors or shingles. The conditioning variables $g1, g2, \dots$ may be omitted.<br>For the <code>data.frame</code> methods, a data frame. |
| data | For the formula methods, an optional data frame in which variables in the  |

	formula (as well as <code>groups</code> and <code>subset</code> , if any) are to be evaluated.
<code>aspect</code>	aspect ratio of each panel (and subpanel), square by default for <code>splom</code> .
<code>between</code>	to avoid confusion between panels and subpanels, the default is to show the panels of a <code>splom</code> plot with space between them.
<code>panel</code>	Usual interpretation for <code>parallel</code> , namely the function that creates the display within each panel. For <code>splom</code> , the terminology is slightly complicated. The role played by the <code>panel</code> function in most other high-level functions is played here by the <code>superpanel</code> function, which is responsible for the display for each conditional data subset. <code>panel</code> is simply an argument to the default <code>superpanel</code> function <code>panel.pairs</code> , and is passed on to it unchanged. It is used there to create each pairwise display. See <a href="#">panel.pairs</a> for more useful options.
<code>superpanel</code>	function that sets up the <code>splom</code> display, by default as a scatterplot matrix.
<code>pscales</code>	a numeric value or a list, meant to be a less functional substitute for the <code>scales</code> argument in <code>xyplot</code> etc. This argument is passed to the <code>superpanel</code> function, and is handled by the default <code>superpanel</code> function <code>panel.pairs</code> . The help page for the latter documents this argument in more detail.
<code>varnames</code>	character vector giving the names of the <code>p</code> variables in <code>x</code> . By default, the column names of <code>x</code> .
<code>horizontal.axis</code>	logical indicating whether the parallel axes should be laid out horizontally (TRUE) or vertically (FALSE).
<code>auto.key</code> , <code>prepanel</code> , <code>scales</code> , <code>strip</code> , <code>groups</code> , <code>xlab</code> , <code>xlim</code> , <code>ylab</code> , <code>ylim</code> , <code>drop.unused.l</code>	See <a href="#">xyplot</a>
<code>...</code>	Further arguments. See corresponding entry in <a href="#">xyplot</a> for non-trivial details.

### Details

`splom` produces Scatter Plot Matrices. The role usually played by `panel` is taken over by `superpanel`, which takes a data frame subset and is responsible for plotting it. It is called with the coordinate system set up to have both `x`- and `y`-limits from 0.5 to `ncol(z) + 0.5`. The only built-in option currently available is [panel.pairs](#), which calls a further panel function for each pair  $(i, j)$  of variables in `z` inside a rectangle of unit width and height centered at  $c(i, j)$  (see [panel.pairs](#) for details).

Many of the finer customizations usually done via arguments to high level function like `xyplot` are instead done by `panel.pairs` for `splom`. These include control of axis limits, tick locations and `prepanel` calculations. If you are trying to fine-tune your `splom` plot, definitely look at the [panel.pairs](#) help page. The `scales` argument is usually not very useful in `splom`, and trying to change it may have undesired effects.

[parallel](#) draws Parallel Coordinate Plots. (Difficult to describe, see example.)

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

### Value

An object of class "trellis". The [update](#) method can be used to update components of the object and the [print](#) method (usually called by default) will plot it on an appropriate plotting device.

      page = function(...) {
        ltext(x = seq(.6, .8, length.out = 4),
              y = seq(.9, .6, length.out = 4),
              labels = c("Three", "Varieties", "of", "Iris"),
              cex = 2)
      })
parallel(~iris[1:4] | Species, iris)
parallel(~iris[1:4], iris, groups = Species,
        horizontal.axis = FALSE, scales = list(x = list(rot = 90)))
```

**Description**

tmd Creates Tukey Mean-Difference Plots from a trellis object returned by `xyplot`, `qq` or `qqmath`. The `prepanel` and `panel` functions are used as appropriate. The formula method for `tmd` is provided for convenience, and simply calls `tmd` on the object created by calling `xyplot` on that formula.

**Usage**

```
tmd(object, ...)
```

```
## S3 method for class 'trellis':
tmd(object,
     xlab = "mean",
     ylab = "difference",
     panel,
     prepanel,
     ...)
```

```

prepanel.tmd.qqmath(x,
                    f.value = NULL,
                    distribution = qnorm,
                    qtype = 7,
                    groups = NULL,
                    subscripts, ...)
panel.tmd.qqmath(x,
                 f.value = NULL,
                 distribution = qnorm,
                 qtype = 7,
                 groups = NULL,
                 subscripts, ...)
panel.tmd.default(x, y, groups = NULL, ...)
prepanel.tmd.default(x, y, ...)

```

### Arguments

<code>object</code>	An object of class "trellis" returned by <code>xyplot</code> , <code>qq</code> or <code>qqmath</code> .
<code>xlab</code>	x label
<code>ylab</code>	y label
<code>panel</code>	panel function to be used. See details below.
<code>prepanel</code>	prepanel function. See details below.
<code>f.value</code> , <code>distribution</code> , <code>qtype</code>	see <a href="#">panel.qqmath</a> .
<code>groups</code> , <code>subscripts</code>	see <a href="#">xyplot</a> .
<code>x</code> , <code>y</code>	data as passed to panel functions in original call.
<code>...</code>	other arguments

### Details

The Tukey Mean-difference plot is produced by modifying the (x,y) values of each panel as follows: the new coordinates are given by  $x = (x+y) / 2$  and  $y = y - x$ , which are then plotted. The default panel function(s) add a reference line at  $y=0$  as well.

`tmd` acts on the a "trellis" object, not on the actual plot this object would have produced. As such, it only uses the arguments supplied to the panel function in the original call, and completely ignores what the original panel function might have done with this data. `tmd` uses these panel arguments to set up its own scales (using its `prepanel` argument) and display (using `panel`). It is thus important to provide suitable `prepanel` and `panel` functions to `tmd` depending on the original call.

Such functions currently exist for `xyplot`, `qq` (the ones with `default` in their name) and `qqmath`, as listed in the usage section above. These assume the default displays for the corresponding high-level call. If unspecified, the `prepanel` and `panel` arguments default to suitable choices.

`tmd` uses the `update` method for "trellis" objects, which processes all extra arguments supplied to `tmd`.

**Value**

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

```

---

B\_10\_rfs

*Residual and Fit Spread Plots*

---

**Description**

Plots fitted values and residuals (via `qqmath`) on a common scale for any object that has methods for fitted values and residuals.

**Usage**

```
rfs(model, layout=c(2, 1), xlab="f-value", ylab=NULL,
     distribution = qunif,
     panel, prepanel, strip, ...)
```

**Arguments**

<code>model</code>	a fitted model object with methods <code>fitted.values</code> and <code>residuals</code> . Can be the value returned by <code>oneway</code>
<code>layout</code>	default layout is <code>c(2,1)</code>
<code>xlab</code>	defaults to <code>"f.value"</code>
<code>distribution</code>	the distribution function to be used for <code>qqmath</code>
<code>ylab</code> , <code>panel</code> , <code>prepanel</code> , <code>strip</code>	See <code>xyplot</code>
<code>...</code>	other arguments, passed on to <code>qqmath</code> .

**Value**

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

B\_11\_oneway

*Fit One-way Model*

---

**Description**

Fits a One-way model to univariate data grouped by a factor, the result often being displayed using `rfs`

**Usage**

```
oneway(formula, data, location=mean, spread=function(x) sqrt(var(x)))
```

**Arguments**

<code>formula</code>	formula of the form $y \sim x$ where $y$ is the numeric response and $x$ is the grouping factor
<code>data</code>	data frame in which the model is to be evaluated
<code>location</code>	function or numeric giving the location statistic to be used for centering the observations, e.g. <code>median</code> , 0 (to avoid centering).
<code>spread</code>	function or numeric giving the spread statistic to be used for scaling the observations, e.g. <code>sd</code> , 1 (to avoid scaling).

**Value**

A list with components

<code>location</code>	vector of locations for each group.
<code>spread</code>	vector of spreads for each group.
<code>fitted.values</code>	vector of locations for each observation.
<code>residuals</code>	residuals ( $y - \text{fitted.values}$ ).
<code>scaled.residuals</code>	residuals scaled by spread for their group

`C_01_trellis.device`*Initializing Trellis Displays*

---

**Description**

Initialization of a display device with appropriate graphical parameters.

**Usage**

```
trellis.device(device = getOption("device"),
              color = !(dev.name == "postscript"),
              theme = lattice.getOption("default.theme"),
              new = TRUE,
              retain = FALSE,
              ...)

standard.theme(name, color)
canonical.theme(name, color)
col.whitebg()
```

**Arguments**

- |                     |   |
|---------------------|---|
| <code>device</code> | function (or the name of one as a character string) that starts a device. Admissible values depend on the platform and how R was compiled (see <a href="#">Devices</a> ), but usually "pdf", "postscript", "png", "jpeg" and at least one of "X11", "windows" and "quartz" will be available.   |
| <code>color</code>  | logical, whether the initial settings should be color or black and white. Defaults to FALSE for postscript devices, TRUE otherwise. Note that this only applies to the initial choice of colors, which can be overridden using <code>theme</code> or subsequent calls to <code>trellis.par.set</code> (and by arguments supplied directly in high level calls for some settings).   |
| <code>theme</code>  | list of components that changes the settings of the device opened, or, a function that when called produces such a list. The function name can be supplied as a quoted string. These settings are only used to modify the default settings (determined by other arguments), and need not contain all possible parameters. A possible use of this argument is to change the default settings by specifying <code>lattice.options(default.theme = "col.whitebg")</code> . For back-compatibility, this is initially (when <code>lattice</code> is loaded) set to <code>options(lattice.theme)</code> .<br>If <code>theme</code> is a function, it will not be supplied any arguments, however, it is guaranteed that a device will already be open when it is called, so one may use <code>.Device</code> inside the function to ascertain what device has been opened. |
| <code>new</code>    | logical flag indicating whether a new device should be started. If FALSE, the options for the current device are changed to the defaults determined by the other arguments.   |
| <code>retain</code> | logical. If TRUE and a setting for this device already exists, then that is used instead of the defaults for this device. By default, pre-existing settings are overwritten (and lost).   |

name name of the device for which the setting is required, as returned by `.Device`  
 ... additional parameters to be passed to the `device` function, most commonly `file` for non-screen devices, as well as `height`, `width`, etc. See the help file for individual devices for admissible arguments.

### Details

Trellis Graphics functions obtain the default values of various graphical parameters (colors, line types, fonts, etc.) from a customizable “settings” list. This functionality is analogous to `par` for standard R graphics and, together with `lattice.options`, mostly supplants it (`par` settings are mostly ignored by Lattice). Unlike `par`, Trellis settings can be controlled separately for each different device type (but not concurrently for different instances of the same device). `standard.theme` and `col.whitebg` produce predefined settings (a.k.a. themes), while `trellis.device` provides a high level interface to control which “theme” will be in effect when a new device is opened. `trellis.device` is called automatically when a “trellis” object is plotted, and the defaults can be used to provide sufficient control, so in a properly configured system it is rarely necessary for the user to call `trellis.device` explicitly.

The `standard.theme` function is intended to provide device specific settings (e.g. light colors on a grey background for screen devices, dark colors or black and white for print devices) which were used as defaults prior to R 2.3.0. However, these defaults are not always appropriate, due to the variety of platforms and hardware settings on which R is used, as well as the fact that a plot created on a particular device may be subsequently used in many different ways. For this reason, a “safe” default is used for all devices from R 2.3.0 onwards. The old behaviour can be reinstated by setting `standard.theme` as the default `theme` argument, e.g. by putting `options(lattice.theme = "standard.theme")` in a startup script (see the entry for `theme` above for details).

### Value

`standard.theme` returns a list of components defining graphical parameter settings for Lattice displays. It is used internally in `trellis.device`, and can also be used as the `theme` argument to `trellis.par.set`, or even as `theme` in `trellis.device` to use the defaults for another device. `canonical.theme` is an alias for `standard.theme`.

`col.whitebg` returns a similar (but smaller) list that is suitable as the `theme` argument to `trellis.device` and `trellis.par.set`. It contains settings values which provide colors suitable for plotting on a white background. Note that the name `col.whitebg` is somewhat of a misnomer, since it actually sets the background to transparent rather than white.

### Note

Earlier versions of `trellis.device` had a `bg` argument to set the background color, but this is no longer supported. If supplied, the `bg` argument will be passed on to the device function; however, this will have no effect on the Trellis settings. It is rarely meaningful to change the background alone; if you feel the need to change the background, consider using the `theme` argument instead.

[Devices](#) for valid choices of device on your platform.

[trellis.par.get](#) and [trellis.par.set](#) can be used to query and modify the settings *after* a device has been initialized. The `par.settings` argument to high level functions, described in [xyplot](#), can be used to attach transient settings to a "trellis" object.

C\_02\_trellis.par.get

*Graphical Parameters for Trellis Displays*

**Description**

Functions used to query, display and modify graphical parameters for fine control of Trellis displays. Modifications are made to the settings for the currently active device only.

**Usage**

```
trellis.par.set(name, value, ..., theme, warn = TRUE, strict = FALSE)
trellis.par.get(name = NULL)
```

```
show.settings(x = NULL)
```

**Arguments**

<code>name</code>	character giving the name of a component. If unspecified, <code>names(trellis.par.get())</code> returns a list containing all the current settings (this can be used to get the valid values for <code>name</code> )
<code>value</code>	a list giving the desired value of the component. Components that are already defined as part of the current settings but are not mentioned in <code>value</code> will remain unchanged.
<code>theme</code>	a list describing how to change the settings, similar to what is returned by <code>trellis.par.get()</code> . This is purely for convenience, allowing multiple calls to <code>trellis.par.set</code> to be condensed into one. The name of each component must be a valid name as described above, with the corresponding value a valid value as described above. As in <a href="#">trellis.device</a> , <code>theme</code> can also be a function that produces such a list when called. The function name can be supplied as a quoted string.
<code>...</code>	Multiple settings can be specified in <code>name = value</code> form. Equivalent to calling with <code>theme = list(...)</code>
<code>warn</code>	logical, indicating whether a warning should be issued when <code>trellis.par.get</code> is called when no graphics device is open
<code>strict</code>	logical, indicating whether the <code>value</code> should be interpreted strictly. Usually, assignment of <code>value</code> to the corresponding named component is fuzzy in the sense that sub-components that are absent from <code>value</code> but not currently <code>NULL</code> are retained. By specifying <code>strict = TRUE</code> , the assignment will be exact.

- x optional list of components that change the settings (any valid value of theme). These are used to modify the current settings (obtained by `trellis.par.get`) before they are displayed.

## Details

The various graphical parameters (color, line type, background etc) that control the look and feel of Trellis displays are highly customizable. Also, R can produce graphics on a number of devices, and it is expected that a different set of parameters would be more suited to different devices. These parameters are stored internally in a variable named `lattice.theme`, which is a list whose components define settings for particular devices. The components are identified by the name of the device they represent (as obtained by `.Device`), and are created as and when new devices are opened for the first time using `trellis.device` (or Lattice plots are drawn on a device for the first time in that session).

The initial settings for each device defaults to values appropriate for that device. In practice, this boils down to three distinct settings, one for screen devices like `x11` and `windows`, one for black and white plots (mostly useful for `postscript`) and one for color printers (`color postscript`, `pdf`).

Once a device is open, its settings can be modified. When another instance of the same device is opened later using `trellis.device`, the settings for that device are reset to its defaults, unless otherwise specified in the call to `trellis.device`. But settings for different devices are treated separately, i.e., opening a `postscript` device will not alter the `x11` settings, which will remain in effect whenever an `x11` device is active.

The functions `trellis.par.*` are meant to be interfaces to the global settings. They always apply on the settings for the currently ACTIVE device.

`trellis.par.get`, called without any arguments, returns the full list of settings for the active device. With the `name` argument present, it returns that component only. `trellis.par.get` sets the value of the `name` component of the current active device settings to `value`.

`trellis.par.get` is usually used inside `trellis` functions to get graphical parameters before plotting. Modifications by users via `trellis.par.set` is traditionally done as follows:

```
add.line <- trellis.par.get("add.line")
add.line$col <- "red"
trellis.par.set("add.line", add.line)
```

More convenient (but not S compatible) ways to do this are

```
trellis.par.set(list(add.line = list(col = "red")))
```

and

```
trellis.par.set(add.line = list(col = "red"))
```

The actual list of the components in `trellis.settings` has not been finalized, so I'm not attempting to list them here. The current value can be obtained by `print(trellis.par.get())`. Most names should be self-explanatory.

`show.settings` provides a graphical display summarizing some of the values in the current settings.

## Value

`trellis.par.get` returns a list giving parameters for that component. If `name` is missing, it returns the full list.

**Note**

In some ways, `trellis.par.get` and `trellis.par.set` together are a replacement for the `par` function used in traditional R graphics. In particular, changing `par` settings has little (if any) effect on lattice output. Since lattice plots are implemented using Grid graphics, its parameter system *does* have an effect unless overridden by a suitable lattice parameter setting. Such parameters can be specified as part of a lattice theme by including them in the `grid.pars` component (see `gpar` for a list of valid parameter names).

One of the uses of `par` is to set `par(ask = TRUE)` making R wait for user input before starting a new graphics page. For Grid graphics, this is done using `grid.prompt`. Lattice has no separate interface for this, and the user must call `grid.prompt` directly. If the grid package is not attached (lattice itself only loads the grid namespace), this may be done using `grid::grid.prompt(TRUE)`.

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

**Examples**

```
show.settings()
```

---

C\_03\_simpleTheme     *Function to generate a simple theme*

---

**Description**

Simple interface to generate a list appropriate as a theme, typically used as the `par.settings` argument in a high level call

**Usage**

```
simpleTheme(col, alpha,
           cex, pch, lty, lwd, font, fill, border,
           col.points, col.line,
           alpha.points, alpha.line)
```

**Arguments**

`col`, `col.points`, `col.line`

A color specification. `col` is used for components `plot.symbol`, `plot.line`, `plot.polygon`, `superpose.symbol`, `superpose.line`, and `superpose.polygon`. `col.points` overrides `col`, and is used only for `plot.symbol` and `superpose.symbol`. Similarly, `col.lines` overrides `col` for `plot.line` and `superpose.line`. The arguments can be vectors, but only the first component is used for scalar targets (i.e., the ones without "superpose" in their name).

<code>alpha</code> , <code>alpha.points</code> , <code>alpha.line</code>	A numeric alpha transparency specification. The same rules as <code>col</code> , etc., apply.
<code>cex</code> , <code>pch</code> , <code>font</code>	Parameters for points. Applicable for components <code>plot.symbol</code> (for which only the first component is used) and <code>superpose.symbol</code> (for which the arguments can be vectors).
<code>lty</code> , <code>lwd</code>	Parameters for lines. Applicable for components <code>plot.line</code> (for which only the first component is used) and <code>superpose.line</code> (for which the arguments can be vectors).
<code>fill</code>	fill color, applicable for components <code>plot.symbol</code> , <code>plot.polygon</code> , <code>superpose.symbol</code> , and <code>superpose.polygon</code> .
<code>border</code>	border color, applicable for components <code>plot.polygon</code> and <code>superpose.polygon</code> .

### Details

The appearance of a lattice display depends partly on the “theme” active when the display is plotted (see `trellis.device` for details). This theme is used to obtain defaults for various graphical parameters, and in particular, the `auto.key` argument works on the premise that the same source is used for both the actual graphical encoding and the legend. The easiest way to specify custom settings for a particular display is to use the `par.settings` argument, which is usually tedious to construct as it is a nested list. The `simpleTheme` function can be used in such situations as a wrapper that generates a suitable list given parameters in simple `name=value` form, with the nesting made implicit. This is less flexible, but straightforward and sufficient in most situations.

### Value

A list that would work as the `theme` argument to `trellis.device` and `trellis.par.set`, or as the `par.settings` argument to any high level lattice function such as `xyplot`.

### Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>, based on a suggestion from John Maindonald.

### See Also

### Examples

```
str(simpleTheme(pch = 16))

dotplot(variety ~ yield | site, data = barley, groups = year,
        auto.key = list(space = "right"),
        par.settings = simpleTheme(pch = 16),
        xlab = "Barley Yield (bushels/acre) ",
        aspect=0.5, layout = c(1,6))
```

---

`C_04_lattice.options`*Low-level Options Controlling Behaviour of Lattice*

---

### Description

Functions to handle settings used by lattice. Their main purpose is to make code maintenance easier, and users normally should not need to use these functions. However, fine control at this level maybe useful in certain cases.

### Usage

```
lattice.options(...)  
lattice.getOption(name)
```

### Arguments

<code>name</code>	character giving the name of a setting
<code>...</code>	new options can be defined, or existing ones modified, using one or more arguments of the form <code>name = value</code> or by passing a list of such tagged values. Existing values can be retrieved by supplying the names (as character strings) of the components as unnamed arguments.

### Details

These functions are modeled on `options` and `getOption`, and behave similarly for the most part. The components currently used are not documented here, but are fairly self-explanatory.

### Value

`lattice.getOption` returns the value of a single component, whereas `lattice.options` always returns a list with one or more named components. When changing the values of components, the old values of the modified components are returned by `lattice.options`. If called without any arguments, the full list is returned.

---

C\_05\_print.trellis *Plot and Summarize Trellis Objects*

---

**Description**

The `print` and `plot` methods produce a graph from a "trellis" object. The `print` method is necessary for automatic plotting. `plot` method is essentially an alias, provided for convenience. The `summary` method gives a textual summary of the object. `dim` and `dimnames` describe the cross-tabulation induced by conditioning. `panel.error` is the default handler used when an error occurs while executing the panel function.

**Usage**

```
## S3 method for class 'trellis':
plot(x, position, split,
     more = FALSE, newpage = TRUE,
     packet.panel = packet.panel.default,
     draw.in = NULL,
     panel.height = lattice.getOption("layout.heights")$panel,
     panel.width = lattice.getOption("layout.widths")$panel,
     save.object = lattice.getOption("save.object"),
     panel.error = lattice.getOption("panel.error"),
     prefix,
     ...)

## S3 method for class 'trellis':
print(x, ...)

## S3 method for class 'trellis':
summary(object, ...)

## S3 method for class 'trellis':
dim(x)
## S3 method for class 'trellis':
dimnames(x)

panel.error(e)
```

**Arguments**

<code>x, object</code>	an object of class "trellis"
<code>position</code>	a vector of 4 numbers, typically <code>c(xmin, ymin, xmax, ymax)</code> that give the lower-left and upper-right corners of a rectangle in which the Trellis plot of <code>x</code> is to be positioned. The coordinate system for this rectangle is [0-1] in both the <code>x</code> and <code>y</code> directions.
<code>split</code>	a vector of 4 integers, <code>c(x,y,nx,ny)</code> , that says to position the current plot at the <code>x,y</code> position in a regular array of <code>nx</code> by <code>ny</code> plots. (Note: this has origin at top left)
<code>more</code>	A logical specifying whether more plots will follow on this page.

<code>newpage</code>	A logical specifying whether the plot should be on a new page. This option is specific to lattice, and is useful for including lattice plots in an arbitrary grid viewport (see the details section).
<code>packet.panel</code>	a function that determines which packet (data subset) is plotted in which panel. Panels are always drawn in an order such that columns vary the fastest, then rows and then pages. This function determines, given the column, row and page and other relevant information, the packet (if any) which should be used in that panel. By default, the association is determined by matching panel order with packet order, which is determined by varying the first conditioning variable the fastest, then the second, and so on. This association rule is encoded in the default, namely the function <code>packet.panel.default</code> , whose help page details the arguments supplied to whichever function is specified as the <code>packet.panel</code> argument.
<code>draw.in</code>	An optional (grid) viewport (used as the <code>name</code> argument in <code>downViewport</code> ) in which the plot is to be drawn. If specified, the <code>newpage</code> argument is ignored. This feature is not well-tested.
<code>panel.width,</code> <code>panel.height</code>	<code>panel.height</code> lists with 2 components, that should be valid <code>x</code> and <code>units</code> arguments to <code>unit()</code> (the <code>data</code> argument cannot be specified currently, but can be considered for addition if needed). The resulting <code>unit</code> object will be the width/height of each panel in the Lattice plot. These arguments can be used to explicitly control the dimensions of the panel, rather than letting them expand to maximize available space. Vector widths are allowed, and can specify unequal lengths across rows or columns.  Note that this option should not be used in conjunction with non-default values of the <code>aspect</code> argument in the original high level call (no error will be produced, but the resulting behaviour is undefined).
<code>save.object</code>	logical, specifying whether the object being printed is to be saved. The last object thus saved can be subsequently retrieved. This is an experimental feature that should allow access to a panel's data after the plot is done, making it possible to enhance the plot after the fact. This also allows the user to invoke the <code>update</code> method on the current plot, even if it was not assigned to a variable explicitly. For more details, see <code>trellis.focus</code> .
<code>panel.error</code>	a function, or a character string naming a function, that is to be executed when an error occurs during the execution of the panel function. The error is caught (using <code>tryCatch</code> ) and supplied as the only argument to <code>panel.error</code> . The default behaviour (implemented as the <code>panel.error</code> function) is to print the corresponding error message in the panel and continue. To stop execution on error, use <code>panel.error = stop</code> .  Normal error recovery and debugging tools are unhelpful when <code>tryCatch</code> is used. <code>tryCatch</code> can be completely bypassed by setting <code>panel.error</code> to <code>NULL</code> .
<code>prefix</code>	character string used as a prefix in viewport and grob names, used to distinguish similar viewports if a page contains multiple plots. The default is based on the serial number of the current plot on the current page (which is one more than the number of plots that have been drawn on the page before the current plot). If supplied explicitly, this has to be a valid R symbol name (briefly, it must start with a letter or a period followed by a letter) and must not contain the grid path separator (currently <code>" : "</code> ).
<code>e</code>	an error condition caught by <code>tryCatch</code>

... extra arguments, ignored by the `print` method. All arguments to the plot method are passed on to the `print` method.

### Details

This is the default print method for objects of class "trellis", produced by calls to functions like `xyplot`, `bwplot` etc. It is usually called automatically when a trellis object is produced. It can also be called explicitly to control plot positioning by means of the arguments `split` and `position`.

When `newpage = FALSE`, the current grid viewport is treated as the plotting area, making it possible to embed a Lattice plot inside an arbitrary grid viewport. The `draw.in` argument provides an alternative mechanism that may be simpler to use.

The print method uses the information in `x` (the object to be printed) to produce a display using the Grid graphics engine. At the heart of the plot is a grid layout, of which the entries of most interest to the user are the ones containing the display panels.

Unlike in older versions of Lattice (and Grid), the grid display tree is retained after the plot is produced, making it possible to access individual viewport locations and make additions to the plot. For more details and a lattice level interface to these viewports, see `trellis.focus`.

### Note

Unlike S-PLUS, trying to position a multipage display (using `position` and/or `split`) will mess things up.

### Examples

```
p11 <- histogram( ~ height | voice.part, data = singer, xlab="Height")
p12 <- densityplot( ~ height | voice.part, data = singer, xlab = "Height")
p2 <- histogram( ~ height, data = singer, xlab = "Height")

## simple positioning by split
print(p11, split=c(1,1,1,2), more=TRUE)
print(p2, split=c(1,2,1,2))

## Combining split and position:
print(p11, position = c(0,0,.75,.75), split=c(1,1,1,2), more=TRUE)
print(p12, position = c(0,0,.75,.75), split=c(1,2,1,2), more=TRUE)
print(p2, position = c(.5,.75,1,1), more=FALSE)

## Using seekViewport

## repeat same plot, with different polynomial fits in each panel
xyplot(Armed.Forces ~ Year, longley, index.cond = list(rep(1, 6)),
       layout = c(3, 2),
       panel = function(x, y, ...)
```

```

    {
      panel.xyplot(x, y, ...)
      fm <- lm(y ~ poly(x, panel.number()))
      llines(x, predict(fm))
    })

## Not run:
grid::seekViewport(trellis.vpname("panel", 1, 1))
cat("Click somewhere inside the first panel:\n")
ltext(grid::grid.locator(), lab = "linear")

## End(Not run)

grid::seekViewport(trellis.vpname("panel", 1, 1))
grid::grid.text("linear")

grid::seekViewport(trellis.vpname("panel", 2, 1))
grid::grid.text("quadratic")

grid::seekViewport(trellis.vpname("panel", 3, 1))
grid::grid.text("cubic")

grid::seekViewport(trellis.vpname("panel", 1, 2))
grid::grid.text("degree 4")

grid::seekViewport(trellis.vpname("panel", 2, 2))
grid::grid.text("degree 5")

grid::seekViewport(trellis.vpname("panel", 3, 2))
grid::grid.text("degree 6")

```

C\_06\_update.trellis

*Retrieve and Update Trellis Object*

---

## Description

Update method for objects of class "trellis", and a way to retrieve the last printed trellis object (that was saved).

## Usage

```

## S3 method for class 'trellis':
update(object,
       panel,
       aspect,
       as.table,
       between,
       key,
       auto.key,
       legend,
       layout,
       main,

```

```

    page,
    par.strip.text,
    prepanel,
    scales,
    skip,
    strip,
    strip.left,
    sub,
    xlab,
    xlim,
    ylab,
    ylim,
    par.settings,
    plot.args,
    lattice.options,
    index.cond,
    perm.cond,
    ...)

## S3 method for class 'trellis':
t(x)

## S3 method for class 'trellis':
x[i, j, ..., drop = FALSE]

trellis.last.object(warn = TRUE, ...)

```

### Arguments

<code>object, x</code>	The object to be updated, of class "trellis".
<code>i, j</code>	indices to be used. Names are not currently allowed.
<code>drop</code>	logical, whether dimensions with only one level are to be dropped. Currently ignored, behaves as if it were FALSE.
<code>warn</code>	logical, whether to warn when no plot is saved.
<code>panel, aspect, as.table, between, key, auto.key, legend, layout, main, page, par</code>	arguments that will be used to update <code>object</code> . See details below.

### Details

All high level lattice functions such as `xyplot` produce an object of (S3) class "trellis", which is usually displayed by its `print` method. However, the object itself can be manipulated and modified to a large extent using the `update` method, and then re-displayed as needed.

Most arguments to high level functions can also be supplied to the `update` method as well, with some exceptions. Generally speaking, anything that would need to change the data within each panel is a no-no (this includes the `formula`, `data`, `groups`, `subscripts` and `subset`). Everything else is technically game, though might not be implemented yet. If you find something missing that you wish to have, feel free to make a request.

Not all arguments accepted by a Lattice function are processed by `update`, but the ones listed above should work. The purpose of these arguments are described in the help page for `xyplot`. Any other argument is added to the list of arguments to be passed to the `panel` function. Because

of their somewhat special nature, updates to objects produced by `cloud` and `wireframe` do not work very well yet.

The `"["` method is a convenient shortcut for updating `index.cond`. The `t` method is a convenient shortcut for updating `perm.cond` in the special (but frequent) case where there are exactly two conditioning variables, when it has the effect of switching ('transposing') their order.

The print method for "trellis" objects optionally saves the object after printing it. If this feature is enabled, `trellis.last.object` can retrieve it. Note that at most one object can be saved at a time. If `trellis.last.object` is called with arguments, these are used to update the retrieved object before returning it.

### Value

An object of class `trellis`, by default plotted by `print.trellis`. `trellis.last.object` returns `NULL` if no saved object is available.

C\_07\_shingles

*shingles*

---

### Description

Functions to handle shingles

### Usage

```
shingle(x, intervals=sort(unique(x)))
equal.count(x, ...)
as.shingle(x)
is.shingle(x)

## S3 method for class 'shingle':
plot(x, panel, xlab, ylab, ...)

## S3 method for class 'shingle':
```

```

print(x, showValues = TRUE, ...)

## S3 method for class 'shingleLevel':
as.character(x, ...)

## S3 method for class 'shingleLevel':
print(x, ...)

## S3 method for class 'shingle':
summary(object, showValues = FALSE, ...)

## S3 method for class 'shingle':
x[subset, drop = FALSE]
as.factorOrShingle(x, subset, drop)

```

### Arguments

<code>x</code>	numeric variable or R object, shingle in <code>plot.shingle</code> and <code>x[]</code> . An object (list of intervals) of class "shingleLevel" in <code>print.shingleLevel</code>
<code>object</code>	shingle object to be summarized
<code>showValues</code>	logical, whether to print the numeric part. If FALSE, only the intervals are printed
<code>intervals</code>	numeric vector or matrix with 2 columns
<code>subset</code>	logical vector
<code>drop</code>	whether redundant shingle levels are to be dropped
<code>panel, xlab, ylab</code>	standard Trellis arguments (see <code>xyplot</code> )
<code>...</code>	other arguments, passed down as appropriate. For example, extra arguments to <code>equal.count</code> are passed on to <code>co.intervals</code> . graphical parameters can be passed as arguments to the <code>plot</code> method.

### Details

A shingle is a data structure used in Trellis, and is a generalization of factors to ‘continuous’ variables. It consists of a numeric vector along with some possibly overlapping intervals. These intervals are the ‘levels’ of the shingle. The `levels` and `nlevels` functions, usually applicable to factors, also work on shingles. The implementation of shingles is slightly different from S.

There are print methods for shingles, as well as for printing the result of `levels()` applied to a shingle. For use in labelling, the `as.character` method can be used to convert levels of a shingle to character strings.

`equal.count` converts `x` to a shingle using the equal count algorithm. This is essentially a wrapper around `co.intervals`. All arguments are passed to `co.intervals`.

`shingle` creates a shingle using the given intervals. If `intervals` is a vector, these are used to form 0 length intervals.

`as.shingle` returns `shingle(x)` if `x` is not a shingle.

`is.shingle` tests whether `x` is a shingle.

`plot.shingle` displays the ranges of shingles via rectangles. `print.shingle` and `summary.shingle` describe the shingle object.

**Value**

x\$intervals for `levels.shingle(x)`, logical for `is.shingle`, an object of class "trellis" for `plot` (printed by default by `print.trellis`), and an object of class "shingle" for the others.

---

D\_draw.colorkey      *Produce a Colorkey for levelplot*

---

**Description**

Produces (and possibly draws) a Grid frame grob which is a colorkey that can be placed in other Grid plots. Used in `levelplot`

**Usage**

```
draw.colorkey(key, draw=FALSE, vp=NULL)
```

**Arguments**

key	A list determining the key. See documentation for <code>levelplot</code> , in particular the section describing the <code>colorkey</code> argument, for details.
draw	logical, whether the grob is to be drawn.
vp	viewport

**Value**

A Grid frame object (that inherits from "grob")

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

[xyplot](#)

---

D\_level.colors                    *A function to compute false colors representing a numeric or categorical variable*

---

**Description**

Calculates false colors from a numeric variable (including factors, using their numeric codes) given a color scheme and breakpoints.

**Usage**

```
level.colors(x, at, col.regions, colors = TRUE, ...)
```

**Arguments**

<code>x</code>	A numeric or <code>factor</code> variable.
<code>at</code>	A numeric variable of breakpoints defining intervals along the range of <code>x</code> .
<code>col.regions</code>	A specification of the colors to be assigned to each interval defined by <code>at</code> . This could be either a vector of colors, or a function that produces a vector of colors when called with a single argument giving the number of colors. See details below.
<code>colors</code>	logical indicating whether colors should be computed and returned. If <code>FALSE</code> , only the indices representing which interval (among those defined by <code>at</code> ) each value in <code>x</code> falls into is returned.
<code>...</code>	Extra arguments, ignored.

**Details**

If `at` has length `n`, then it defines `n-1` intervals. Values of `x` outside the range of `at` are not assigned to an interval, and the return value is `NA` for such values.

Colors are chosen by assigning a color to each of the `n-1` intervals. If `col.regions` is a palette function (such as `topo.colors`, or the result of calling `colorRampPalette`), it is called with `n-1` as an argument to obtain the colors. Otherwise, if there are exactly `n-1` colors in `col.regions`, these get assigned to the intervals. If there are fewer than `n-1` colors, `col.regions` gets recycled. If there are more, a more or less equally spaced (along the length of `col.regions`) subset is chosen.

**Value**

A vector of the same length as `x`. Depending on the `colors` argument, this could be either a vector of colors (in a form usable by `R`), or a vector of integer indices representing which interval the values of `x` fall in.

**Author(s)**

Deepayan Sarkar <deepayan.sarkar@r-project.org>

**See Also**

[levelplot](#), [colorRampPalette](#).

**Examples**

```
depth.col <-
  with(quakes,
       level.colors(depth, at = do.breaks(range(depth), 30),
                   col.regions = terrain.colors))

xyplot(lat ~ long | equal.count(stations), quakes,
       strip = strip.custom(var.name = "Stations"),
       colours = depth.col,
       panel = function(x, y, colours, subscripts, ...) {
         panel.xyplot(x, y, pch = 21, col = "transparent",
                     fill = colours[subscripts], ...)
       })
```

---

`D_make.groups`*Grouped data from multiple vectors*

---

**Description**

Combines two or more vectors, possibly of different lengths, producing a data frame with a second column indicating which of these vectors that row came from. This is mostly useful for getting data into a form suitable for use in high level Lattice functions.

**Usage**

```
make.groups(...)
```

**Arguments**

`...` one or more vectors of the same type (coercion is attempted if not), or one or more data frames with similar columns, with possibly differing number of rows.

**Value**

When all the input arguments are vectors, a data frame with two columns

`data` all the vectors supplied, concatenated

`which` factor indicating which vector the corresponding data value came from

When all the input arguments are data frames, the result of `rbind` applied to them, along with an additional `which` column as described above.

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

**See Also**

[Lattice](#)

**Examples**

```
sim.dat <-
  make.groups(uniform = runif(200),
             exponential = rexp(175),
             lognormal = rlnorm(150),
             normal = rnorm(125))
qqmath(~ data | which, sim.dat, scales = list(y = "free"))
```

---

D\_simpleKey                      *Function to generate a simple key*

---

### Description

Simple interface to generate a list appropriate for `draw.key`

### Usage

```
simpleKey(text, points = TRUE,
         rectangles = FALSE,
         lines = FALSE,
         col, cex, alpha, font,
         fontface, fontfamily,
         lineheight, ...)
```

### Arguments

<code>text</code>	character or expression vector, to be used as labels for levels of the grouping variable
<code>points</code>	logical
<code>rectangles</code>	logical
<code>lines</code>	logical
<code>col, cex, alpha, font, fontface, fontfamily, lineheight</code>	Used as top-level components of the list produced, to be used for the text labels. Defaults to the values in <code>trellis.par.get("add.text")</code>
<code>...</code>	further arguments added to the list, eventually passed to <code>draw.key</code>

### Details

A lattice plot can include a legend (key) if an appropriate list is specified as the `key` argument to a high level Lattice function such as `xyplot`. This key can be very flexible, but that flexibility comes at a cost: this list needs to be fairly complicated even in simple situations. `simpleKey` is designed as a useful shortcut in the common case of a key drawn in conjunction with a grouping variable, using the default graphical settings.

The `simpleKey` function produces a suitable `key` argument using a simpler interface. The resulting list will use the `text` argument as a text component, along with at most one set each of points, rectangles, and lines. The number of entries (rows) in the key will be the length of the `text` component. The graphical parameters for the additional components will be derived from the default graphical settings (wherein lies the simplification, as otherwise these would have to be provided explicitly).

Calling `simpleKey` directly is usually unnecessary. It is most commonly invoked (during the plotting of the "trellis" object) when the `auto.key` argument is supplied in a high-level plot with a `groups` argument. In that case, the `text` argument of `simpleKey` defaults to `levels(groups)`, and the defaults for the other arguments depend on the relevant high-level function. Note that these defaults can be overridden by supplying `auto.key` as a list containing the replacement values.

**Value**

A list that would work as the `key` argument to `xyplot`, etc.

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

**See Also**

`Lattice`, `draw.key`, `trellis.par.get`, and `xyplot`, specifically the entry for `auto.key`.

---

D\_strip.default      *Default Trellis Strip Function*

---

**Description**

`strip.default` is the function that draws the strips by default in Trellis plots. Users can write their own strip functions, but most commonly this involves calling `strip.default` with a slightly different arguments. `strip.custom` provides a convenient way to obtain new strip functions that differ from `strip.default` only in the default values of certain arguments.

**Usage**

```
strip.default(which.given,
             which.panel,

             var.name,
             factor.levels,
             shingle.intervals,
             strip.names = c(FALSE, TRUE),
             strip.levels = c(TRUE, FALSE),
             sep = " : ",
             style = 1,
             horizontal = TRUE,
             bg = trellis.par.get("strip.background")$col[which.given],
             fg = trellis.par.get("strip.shingle")$col[which.given],
             par.strip.text = trellis.par.get("add.text"))
strip.custom(...)
```

**Arguments**

`which.given` integer index specifying which of the conditioning variables this strip corresponds to.

`which.panel` vector of integers as long as the number of conditioning variables. The contents are indices specifying the current levels of each of the conditioning variables (thus, this would be unique for each distinct packet). This is identical to the return value of `which.packet`, which is a more accurate name.

<code>var.name</code>	vector of character strings or expressions as long as the number of conditioning variables. The contents are interpreted as names for the conditioning variables. Whether they are shown on the strip depends on the values of <code>strip.names</code> and <code>style</code> (see below). By default, the names are shown for shingles, but not for factors.
<code>factor.levels</code>	vector of character strings or expressions giving the levels of the conditioning variable currently being drawn. For more than one conditioning variable, this will vary with <code>which.given</code> . Whether these levels are shown on the strip depends on the values of <code>strip.levels</code> and <code>style</code> (see below). <code>factor.levels</code> may be specified for both factors and shingles (despite the name), but by default they are shown only for factors. If shown, the labels may optionally be abbreviated by specifying suitable components in <code>par.strip.text</code> (see <a href="#">xyplot</a> )
<code>shingle.intervals</code>	if the current strip corresponds to a shingle, this should be a 2-column matrix giving the levels of the shingle. (of the form that would be produced by <code>printing.levels(shingle)</code> ). Otherwise, it should be <code>NULL</code>
<code>strip.names</code>	a logical vector of length 2, indicating whether or not the name of the conditioning variable that corresponds to the strip being drawn is to be written on the strip. The two components give the values for factors and shingles respectively. This argument is ignored for a factor when <code>style</code> is not one of 1 and 3.
<code>strip.levels</code>	a logical vector of length 2, indicating whether or not the level of the conditioning variable that corresponds to the strip being drawn is to be written on the strip. The two components give the values for factors and shingles respectively.
<code>sep</code>	character or expression, serving as a separator if the name and level are both to be shown.
<code>style</code>	integer, with values 1, 2, 3, 4 and 5 currently supported, controlling how the current level of a factor is encoded. Ignored for shingles (actually, when <code>shingle.intervals</code> is non-null. <p>The best way to find out what effect the value of <code>style</code> has is to try them out. Here is a short description: for a style value of 1, the strip is colored in the background color with the strip text (as determined by other arguments) centered on it. A value of 3 is the same, except that a part of the strip is colored in the foreground color, indicating the current level of the factor. For styles 2 and 4, the part corresponding to the current level remains colored in the foreground color, however, for style = 2, the remaining part is not colored at all, whereas for 4, it is colored with the background color. For both these, the names of all the levels of the factor are placed on the strip from left to right. Styles 5 and 6 produce the same effect (they are subtly different in S, this implementation corresponds to 5), they are similar to style 1, except that the strip text is not centered, it is instead positioned according to the current level.</p> <p>Note that unlike S-PLUS, the default value of <code>style</code> is 1. <code>strip.names</code> and <code>strip.levels</code> have no effect if <code>style</code> is not 1 or 3.</p>
<code>horizontal</code>	logical, specifying whether the labels etc should be horizontal. <code>horizontal=FALSE</code> is useful for strips on the left of panels using <code>strip.left=TRUE</code>
<code>par.strip.text</code>	list with parameters controlling the text on each strip, with components <code>col</code> , <code>cex</code> , <code>font</code> , etc.

bg	strip background color.
fg	strip foreground color.
...	arguments to be passed on to <code>strip.default</code> , overriding whatever value it would have normally assumed

### Details

default strip function for trellis functions. Useful mostly because of the `style` argument — non-default styles are often more informative, especially when the names of the levels of the factor `x` are small. Traditional use is as `strip = function(...) strip.default(style=2,...)`, though this can be simplified by the use of `strip.custom`.

### Value

`strip.default` is called for its side-effect, which is to draw a strip appropriate for multi-panel Trellis conditioning plots. `strip.custom` returns a function that is similar to `strip.default`, but with different defaults for the arguments specified in the call.

### Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

### Examples

```
## Traditional use
xyplot(Petal.Length ~ Petal.Width | Species, iris,
       strip = function(..., style) strip.default(..., style = 4))

## equivalent call using strip.custom
xyplot(Petal.Length ~ Petal.Width | Species, iris,
       strip = strip.custom(style = 4))

xyplot(Petal.Length ~ Petal.Width | Species, iris,
       strip = FALSE,
       strip.left = strip.custom(style = 4, horizontal = FALSE))
```

---

D\_trellis.object    *A Trellis Plot Object*

---

### Description

This class of objects is returned by high level lattice functions, and is usually plotted by default by its `print` method.

**Details**

A trellis object, as returned by high level lattice functions like `xyplot`, is a list with the "class" attribute set to "trellis". Many of the components of this list are simply the arguments to the high level function that produced the object. Among them are: `as.table`, `layout`, `page`, `panel`, `prepanel`, `main`, `sub`, `par.strip.text`, `strip`, `skip`, `xlab` `ylab`, `par.settings`, `lattice.options` and `plot.args`. Some other typical components are:

`formula` the Trellis formula used in the call  
`index.cond` list with index for each of the conditioning variables  
`perm.cond` permutation of the order of the conditioning variables  
`aspect.fill` logical, whether aspect is "fill"  
`aspect.ratio` numeric, aspect ratio to be used if `aspect.fill` is FALSE  
`call` call that generated the object.  
`condlevels` list with levels of the conditioning variables  
`legend` list describing the legend(s) to be drawn  
`panel.args` a list as long as the number of panels, each element being a list itself, containing the arguments in named form to be passed to the panel function in that panel.  
`panel.args.common` a list containing the arguments common to all the panel functions in name=value form  
`x.scales` list describing x-scale, can consist of several other lists, paralleling `panel.args`, if x-relation is not "same"  
`y.scales` list describing y-scale, similar to `x.scales`  
`x.between` numeric vector of interpanel x-space  
`y.between` numeric vector of interpanel y-space  
`x.limits` numeric vector of length 2 or list, giving x-axis limits  
`y.limits` similar to `x.limits`  
`packet.sizes` array recording the number of observations in each packet

**See Also**

[Lattice](#), [xyplot](#), [print.trellis](#)

**Description**

The classic Trellis paradigm is to plot the whole object at once, without the possibility of interacting with it afterwards. However, by keeping track of the grid viewports where the panels and strips are drawn, it is possible to go back to them afterwards and enhance them one panel at a time. These functions provide convenient interfaces to help in this. Note that these are still experimental and the exact details may change in future.

**Usage**

```

panel.identify(x, y = NULL,
              subscripts = seq_along(x),
              labels = subscripts,
              n = length(x), offset = 0.5,
              threshold = 18, ## in points, roughly 0.25 inches
              panel.args = trellis.panelArgs(),
              ...)
panel.identify.qqmath(x, distribution, groups, subscripts, labels,
                    panel.args = trellis.panelArgs(),
                    ...)
panel.identify.cloud(x, y, z, subscripts,
                   perspective, distance,
                   xlim, ylim, zlim,
                   screen, R.mat, aspect, scales.3d,
                   ...,
                   panel.3d.identify,
                   n = length(subscripts),
                   offset = 0.5,
                   threshold = 18,
                   labels = subscripts,
                   panel.args = trellis.panelArgs())
panel.link.splom(threshold = 18, verbose = getOption("verbose"), ...)
panel.brush.splom(threshold = 18, verbose = getOption("verbose"), ...)

trellis.vpname(name = c("position", "split", "split.location", "toplevel",
                      "figure", "panel", "strip", "strip.left", "legend",
                      "main", "sub", "xlab", "ylab", "page"),
              column, row,
              side = c("left", "top", "right", "bottom", "inside"),
              clip.off = FALSE, prefix)
trellis.grobname(name, prefix)
trellis.focus(name, column, row, side, clip.off,
             highlight = interactive(), ...,
             guess = TRUE, verbose = getOption("verbose"))
trellis.switchFocus(name, side, clip.off, highlight, ...)
trellis.unfocus()
trellis.panelArgs(x, packet.number)

```

**Arguments**

*x*, *y*, *z*        variables defining the contents of the panel. In the case of `trellis.panelArgs`, a "trellis" object.

*n*                the number of points to identify by default (overridden by a right click)

*subscripts*      an optional vector of integer indices associated with each point. See details below.

*labels*          an optional vector of labels associated with each point. Defaults to `subscripts`

*distribution*, *groups*    typical panel arguments of `panel.qqmath`. These will usually be obtained from `panel.args`

<code>offset</code>	the labels are printed either below, above, to the left or to the right of the identified point, depending on the relative location of the mouse click. The <code>offset</code> specifies (in "char" units) how far from the identified point the labels should be printed.
<code>threshold</code>	threshold in grid's "points" units. Points further than these from the mouse click position are not considered
<code>panel.args</code>	list that contains components names <code>x</code> (and usually <code>y</code> ), to be used if <code>x</code> is missing. Typically, when called after <code>trellis.focus</code> , this would appropriately be the arguments passed to that panel.
<code>perspective, distance, xlim, ylim, zlim, screen, R.mat, aspect, scales.3d</code>	arguments as passed to <code>panel.cloud</code> . These are required to recompute the relevant three-dimensional projections in <code>panel.identify.cloud</code> .
<code>panel.3d.identify</code>	the function that is responsible for the actual interaction once the data rescaling and rotation computations have been done. By default, an internal function similar to <code>panel.identify</code> is used.
<code>name</code>	<p>character string indicating which viewport or grob we are looking for. Although these do not necessarily provide access to all viewports and grobs created by a lattice plot, they cover most that users might find interesting.</p> <p><code>trellis.vpname</code> and <code>trellis.focus</code> deal with viewport names only, and only accept the values explicitly listed above. <code>trellis.grobname</code> is meant to create names for grobs, and can currently accept any value.</p> <p>If <code>name</code>, as well as <code>column</code> and <code>row</code> is missing in a call to <code>trellis.focus</code>, the user can click inside a panel (or an associated strip) to focus on that panel. Note however that this assumes equal width and height for each panel, and may not work when this is not true.</p> <p>When <code>name</code> is "panel", "strip", or "strip.left", <code>column</code> and <code>row</code> must also be specified. When <code>name</code> is "legend", <code>side</code> must also be specified.</p>
<code>column, row</code>	integers, indicating position of the panel or strip that should be assigned focus in the Trellis layout. Rows are usually calculated from the bottom up, unless the plot was created with <code>as.table=TRUE</code>
<code>guess</code>	logical. If <code>TRUE</code> , and the display has only one panel, that panel will be automatically selected by a call to <code>trellis.focus</code> .
<code>side</code>	character string, relevant only for legends (i.e., when <code>name="legend"</code> ), indicating their position. Partial specification is allowed, as long as it is unambiguous.
<code>clip.off</code>	logical, whether clipping should be off, relevant when <code>name</code> is "panel" or "strip". This is necessary if axes are to be drawn outside the panel or strip. Note that setting <code>clip.off=FALSE</code> does not necessarily mean that clipping is on; that is determined by conditions in effect during printing.
<code>prefix</code>	character string acting as a prefix, meant to distinguish otherwise equivalent viewports in different plots. This only becomes relevant when a particular page is occupied by more than one plot. Defaults to the value appropriate for the last "trellis" object printed, as determined by the <code>prefix</code> argument in <code>print.trellis</code> . Users should not usually need to supply a value for this argument (see note below), however, if supplied explicitly, this has to be a valid R symbol name (briefly, it must start with a letter or a period followed by a letter) and must not contain the grid path separator (currently " : ")

<code>highlight</code>	logical, whether the viewport being assigned focus should be highlighted. For <code>trellis.focus</code> , the default is <code>TRUE</code> in interactive mode, and <code>trellis.switchFocus</code> by default preserves the setting currently active.
<code>packet.number</code>	integer, which panel to get data from. See <code>packet.number</code> for details on how this is calculated
<code>verbose</code>	whether details will be printed
<code>...</code>	For <code>panel.identify.qqmath</code> , extra parameters are passed on to <code>panel.identify</code> . For <code>panel.identify</code> , extra arguments are treated as graphical parameters and are used for labelling. For <code>trellis.focus</code> and <code>trellis.switchFocus</code> , these are used (in combination with <code>lattice.options</code> ) for highlighting the chosen viewport if so requested. Graphical parameters can be supplied for <code>panel.link.splom</code> .

## Details

`panel.identify` is similar to `identify`. When called, it waits for the user to identify points (in the panel being drawn) via mouse clicks. Clicks other than left-clicks terminate the procedure. Although it is possible to call it as part of the panel function, it is more typical to use it to identify points after plotting the whole object, in which case a call to `trellis.focus` first is necessary.

`panel.link.splom` is meant for use with `spлом`, and requires a panel to be chosen using `trellis.focus` before it is called. Clicking on a point causes that and the corresponding projections in other pairwise scatter plots to be highlighted. `panel.brush.splom` is a (misnamed) alias for `panel.link.splom`, retained for back-compatibility.

`panel.identify.qqmath` is a specialized wrapper meant for use with the display produced by `qqmath`. `panel.identify.cloud` is a specialized wrapper meant for use with the display produced by `cloud`. It would be unusual to call them except in a context where default panel function arguments are available through `trellis.panelArgs` (see below).

One way in which `panel.identify` etc. are different from `identify` is in how it uses the `subscripts` argument. In general, when one identifies points in a panel, one wants to identify the origin in the data frame used to produce the plot, and not within that particular panel. This information is available to the panel function, but only in certain situations. One way to ensure that `subscripts` is available is to specify `subscripts = TRUE` in the high level call such as `xyplot`. If `subscripts` is not explicitly specified in the call to `panel.identify`, but is available in `panel.args`, then those values will be used. Otherwise, they default to `seq_along(x)`. In either case, the final return value will be the `subscripts` that were marked.

The process of printing (plotting) a Trellis object builds up a grid layout with named viewports which can then be accessed to modify the plot further. While full flexibility can only be obtained by using grid functions directly, a few lattice functions are available for the more common tasks.

`trellis.focus` can be used to move to a particular panel or strip, identified by its position in the array of panels. It can also be used to focus on the viewport corresponding to one of the labels or a legend, though such usage would be less useful. The exact viewport is determined by the name along with the other arguments, not all of which are relevant for all names. Note that when more than one object is plotted on a page, `trellis.focus` will always go to the plot that was created last. For more flexibility, use grid functions directly (see note below).

After a successful call to `trellis.focus`, the desired viewport (typically panel or strip area) will be made the 'current' viewport (plotting area), which can then be enhanced by calls to standard lattice panel functions as well as grid functions.

It is quite common to have the layout of panels chosen when a "trellis" object is drawn, and not before then. Information on the layout (specifically, how many rows and columns, and which

packet belongs in which position in this layout) is retained for the last "trellis" object plotted, and is available through `trellis.currentLayout`.

`trellis.unfocus` unsets the focus, and makes the top level viewport the current viewport.

`trellis.switchFocus` is a convenience function to switch from one viewport to another, while preserving the current `row` and `column`. Although the rows and columns only make sense for panels and strips, they would be preserved even when the user switches to some other viewport (where row/column is irrelevant) and then switches back.

Once a panel or strip is in focus, `trellis.panelArgs` can be used to retrieve the arguments that were available to the panel function at that position. In this case, it can be called without arguments as

```
trellis.panelArgs()
```

This usage is also allowed when a "trellis" object is being printed, e.g. inside the panel functions or the axis function (but not inside the prepanel function). `trellis.panelArgs` can also retrieve the panel arguments from any "trellis" object. Note that for this usage, one needs to specify the `packet.number` (as described under the `panel` entry in [xyplot](#)) and not the position in the layout, because a layout determines the panel only **after** the object has been printed.

It is usually not necessary to call `trellis.vpname` and `trellis.grobname` directly. However, they can be useful in generating appropriate names in a portable way when using grid functions to interact with the plots directly, as described in the note below.

## Value

`panel.identify` returns an integer vector containing the subscripts of the identified points (see details above). The equivalent of `identify` with `pos=TRUE` is not yet implemented, but can be considered for addition if requested.

`trellis.panelArgs` returns a named list of arguments that were available to the panel function for the chosen panel.

`trellis.vpname` and `trellis.grobname` return character strings.

`trellis.focus` has a meaningful return value only if it has been used to focus on a panel interactively, in which case the return value is a list with components `col` and `row` giving the column and row positions respectively of the chosen panel, unless the choice was cancelled (by a right click), in which case the return value is `NULL`. If click was outside a panel, both `col` and `row` are set to 0.

## Note

The viewports created by `lattice` is accessible to the user only up to a certain extent, as described above. In particular, `trellis.focus` can only be used to manipulate the last plot drawn. For full flexibility, use appropriate functions from the `grid` package directly. For example, `current.vpTree` can be used to inspect the current viewport tree and `seekViewport` or `downViewport` can be used to navigate to these viewports. For such usage, `trellis.vpname` and `trellis.grobname` (with a non-default `prefix` argument) provides a portable way to access the appropriate viewports and grobs by name.

## Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>. Felix Andrews provided initial implementations of `panel.identify.qqmath` and support for focusing on panels interactively.

---

F\_1\_panel.barchart *Default Panel Function for barchart*

---

## Description

Default panel function for barchart.

## Usage

```

panel.barchart(x, y, box.ratio = 1, box.width,
               horizontal = TRUE,
               origin = NULL, reference = TRUE,
               stack = FALSE,
               groups = NULL,
               col = if (is.null(groups)) plot.polygon$col
                       else superpose.polygon$col,
               border = if (is.null(groups)) plot.polygon$border
                         else superpose.polygon$border,
               lty = if (is.null(groups)) plot.polygon$lty
                      else superpose.polygon$lty,
               lwd = if (is.null(groups)) plot.polygon$lwd
                       else superpose.polygon$lwd,
               ...)

```

## Arguments

x	Extent of Bars. By default, bars start at left of panel, unless origin is specified, in which case they start there
y	Horizontal location of bars, possibly factor
box.ratio	ratio of bar width to inter-bar space

<code>box.width</code>	thickness of bars in absolute units; overrides <code>box.ratio</code> . Useful for specifying thickness when the categorical variable is not a factor, as use of <code>box.ratio</code> alone cannot achieve a thickness greater than 1.
<code>horizontal</code>	logical. If <code>FALSE</code> , the plot is ‘transposed’ in the sense that the behaviours of <code>x</code> and <code>y</code> are switched. <code>x</code> is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of <code>bwplot</code> for a fuller explanation.
<code>origin</code>	the origin for the bars. For grouped displays with <code>stack = TRUE</code> , this argument is ignored and the origin set to 0. Otherwise, defaults to <code>NULL</code> , in which case bars start at the left (or bottom) end of a panel. This choice is somewhat unfortunate, as it can be misleading, but is the default for historical reasons. For tabular (or similar) data, <code>origin = 0</code> is usually more appropriate; if not, one should reconsider the use of a bar chart in the first place (dot plots are often a good alternative).
<code>reference</code>	logical, whether a reference line is to be drawn at the origin
<code>stack</code>	logical, relevant when <code>groups</code> is non-null. If <code>FALSE</code> (the default), bars for different values of the grouping variable are drawn side by side, otherwise they are stacked.
<code>groups</code>	optional grouping variable
<code>col, border, lty, lwd</code>	Graphical parameters for the bars. By default, the trellis parameter <code>plot.polygon</code> is used if there is no grouping variable, otherwise <code>superpose.polygon</code> is used. <code>col</code> gives the fill color, <code>border</code> the border color, and <code>lty</code> and <code>lwd</code> the line type and width of the borders.
<code>...</code>	extra arguments will be accepted but ignored

### Details

A barchart is drawn in the panel. Note that most arguments controlling the display can be supplied to the high-level `barchart` call directly.

---

F\_1\_panel.bwplot     *Default Panel Function for bwplot*

---

### Description

This is the default panel function for `bwplot`.

**Usage**

```
panel.bwplot(x, y, box.ratio = 1,
             box.width = box.ratio / (1 + box.ratio),
             horizontal = TRUE,
             pch, col, alpha, cex,
             font, fontfamily, fontface,
             fill, varwidth = FALSE,
             notch = FALSE, notch.frac = 0.5,
             ...,
             levels.fos,
             stats = boxplot.stats,
             coef = 1.5,
             do.out = TRUE)
```

**Arguments**

<code>x, y</code>	numeric vector or factor. Boxplots drawn for each unique value of <code>y</code> ( <code>x</code> ) if <code>horizontal</code> is <code>TRUE</code> ( <code>FALSE</code> )
<code>box.ratio</code>	ratio of box thickness to inter box space
<code>box.width</code>	thickness of box in absolute units; overrides <code>box.ratio</code> . Useful for specifying thickness when the categorical variable is not a factor, as use of <code>box.ratio</code> alone cannot achieve a thickness greater than 1.
<code>horizontal</code>	logical. If <code>FALSE</code> , the plot is ‘transposed’ in the sense that the behaviours of <code>x</code> and <code>y</code> are switched. <code>x</code> is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of <a href="#">bwplot</a> for a fuller explanation.
<code>pch, col, alpha, cex, font, fontfamily, fontface</code>	graphical parameters controlling the dot. <code>pch=" "</code> is treated specially, by replacing the dot with a line (similar to <a href="#">boxplot</a> )
<code>fill</code>	color to fill the boxplot
<code>varwidth</code>	logical. If <code>TRUE</code> , widths of boxplots are proportional to the number of points used in creating it.
<code>notch</code>	if <code>notch</code> is <code>TRUE</code> , a notch is drawn in each side of the boxes. If the notches of two plots do not overlap this is ‘strong evidence’ that the two medians differ (Chambers et al., 1983, p. 62). See <a href="#">boxplot.stats</a> for the calculations used.
<code>notch.frac</code>	numeric in (0,1). When <code>notch=TRUE</code> , the fraction of the box width that the notches should use.
<code>stats</code>	a function, defaulting to <a href="#">boxplot.stats</a> , that accepts a numeric vector and returns a list similar to the return value of <a href="#">boxplot.stats</a> . The function must accept arguments <code>coef</code> and <code>do.out</code> even if they do not use them (a <code>...</code> argument is good enough). This function is used to determine the box and whisker plot.
<code>coef, do.out</code>	passed to <code>stats</code>
<code>levels.fos</code>	numeric values corresponding to positions of the factor or shingle variable. For internal use.
<code>...</code>	further arguments, ignored.

**Details**

Creates Box and Whisker plot of  $x$  for every level of  $y$  (or the other way round if `horizontal=FALSE`). By default, the actual boxplot statistics are calculated using `boxplot.stats`. Note that most arguments controlling the display can be supplied to the high-level `bwplot` call directly.

Although the graphical parameters for the dot representing the median can be controlled by optional arguments, many others can not. These parameters are obtained from the relevant settings parameters ("`box.rectangle`" for the box, "`box.umbrella`" for the whiskers and "`plot.symbol`" for the outliers).

       notch = TRUE, pch = "|")
```

---

F\_1\_panel.cloud

*Default Panel Function for cloud*

---

**Description**

These are default panel functions controlling `cloud` and `wireframe` displays.

**Usage**

```
panel.cloud(x, y, subscripts, z,
            groups = NULL,
            perspective = TRUE,
            distance = if (perspective) 0.2 else 0,
            xlim, ylim, zlim,
            panel.3d.cloud = "panel.3dscatter",
            panel.3d.wireframe = "panel.3dwire",
            screen = list(z = 40, x = -60),
            R.mat = diag(4), aspect = c(1, 1),
```

```

par.box = NULL,
xlab, ylab, zlab,
xlab.default, ylab.default, zlab.default,
scales.3d,
proportion = 0.6,
wireframe = FALSE,
scpos,
...,
at)
panel.wireframe(...)
panel.3dscatter(x, y, z, rot.mat, distance,
               groups, type = "p",
               xlim.scaled, ylim.scaled, zlim.scaled,
               zero.scaled,
               col, col.point, col.line,
               lty, lwd, cex, pch,
               cross, ..., subscripts)
panel.3dwire(x, y, z, rot.mat = diag(4), distance,
             shade = FALSE,
             shade.colors.palette = trellis.par.get("shade.colors")$palette,
             light.source = c(0, 0, 1000),
             xlim.scaled,
             ylim.scaled,
             zlim.scaled,
             col = if (shade) "transparent" else "black",
             lty = 1, lwd = 1,
             alpha,
             col.groups = superpose.polygon$col,
             polynum = 100,
             ...,
             drape = FALSE,
             at,
             col.regions = regions$col,
             alpha.regions = regions$alpha)

```

### Arguments

`x`, `y`, `z` numeric (or possibly factors) vectors representing the data to be displayed. The interpretation depends on the context. For `panel.cloud` these are essentially the same as the data passed to the high level plot (except if `formula` was a matrix, the appropriate `x` and `y` vectors are generated). By the time they are passed to `panel.3dscatter` and `panel.3dwire`, they have been appropriately subsetted (using `subscripts`) and scaled (to lie inside a bounding box, usually the [-0.5, 0.5] cube).  
Further, for `panel.3dwire`, `x` and `y` are shorter than `z` and represent the sorted locations defining a rectangular grid. Also in this case, `z` may be a matrix if the display is grouped, with each column representing one surface.  
In `panel.cloud` (called from `wireframe`) and `panel.3dwire`, `x`, `y` and `z` could also be matrices (of the same dimension) when they represent a 3-D surface parametrized on a 2-D grid.

`subscripts` index specifying which points to draw. The same `x`, `y` and `z` values (representing the whole data) are passed to `panel.cloud` for each panel. `subscripts`

	specifies the subset of rows to be used for the particular panel.
groups	specification of a grouping variable, passed down from the high level functions.
perspective	logical, whether to plot a perspective view. Setting this to FALSE is equivalent to setting distance to 0
distance	numeric, between 0 and 1, controls amount of perspective. The distance of the viewing point from the origin (in the transformed coordinate system) is $1 / \text{distance}$ . This is described in a little more detail in the documentation for <code>cloud</code>
screen	A list determining the sequence of rotations to be applied to the data before being plotted. The initial position starts with the viewing point along the positive z-axis, and the x and y axes in the usual position. Each component of the list should be named one of "x", "y" or "z" (repetitions are allowed), with their values indicating the amount of rotation about that axis in degrees.
R.mat	initial rotation matrix in homogeneous coordinates, to be applied to the data before <code>screen</code> rotates the view further.
par.box	graphical parameters for box, namely, col, lty and lwd. By default obtained from the parameter <code>box.3d</code>
xlim, ylim, zlim	limits for the respective axes. As with other lattice functions, these could each be a numeric 2-vector or a character vector indicating levels of a factor.
panel.3d.cloud, panel.3d.wireframe	functions that draw the data-driven part of the plot (as opposed to the bounding box and scales) in <code>cloud</code> and <code>wireframe</code> . This function is called after the 'back' of the bounding box is drawn, but before the 'front' is drawn. Any user-defined custom display would probably want to change these functions. The intention is to pass as much information to this function as might be useful (not all of which are used by the defaults). In particular, these functions can expect arguments called <code>xlim</code> , <code>ylim</code> , <code>zlim</code> which give the bounding box ranges in the original data scale and <code>xlim.scaled</code> , <code>ylim.scaled</code> , <code>zlim.scaled</code> which give the bounding box ranges in the transformed scale. More arguments can be considered on request.
aspect	aspect as in <code>cloud</code>
xlab, ylab, zlab	Labels, have to be lists. Typically the user will not manipulate these, but instead control this via arguments to <code>cloud</code> directly.
xlab.default	for internal use
ylab.default	for internal use
zlab.default	for internal use
scales.3d	list defining the scales
proportion	numeric scalar, gives the length of arrows as a proportion of the sides
scpos	A list with three components x, y and z (each a scalar integer), describing which of the 12 sides of the cube the scales should be drawn. The defaults should be OK. Valid values are x: 1, 3, 9, 11; y: 8, 5, 7, 6 and z: 4, 2, 10, 12. (See comments in the source code of <code>panel.cloud</code> to see the details of this enumeration.)
wireframe	logical, indicating whether this is a wireframe plot
drape	logical, whether the facets will be colored by height, in a manner similar to <code>levelplot</code> . This is ignored if <code>shade=TRUE</code> .

`at`, `col.regions`, `alpha.regions`  
 deals with specification of colors when `drape = TRUE` in `wireframe`.  
`at` can be a numeric vector, `col.regions` a vector of colors, and  
`alpha.regions` a numeric scalar controlling transparency. The resulting be-  
 haviour is similar to `levelplot`, `at` giving the breakpoints along the z-axis  
 where colors change, and the other two determining the colors of the facets that  
 fall in between.

`rot.mat` 4x4 transformation matrix in homogeneous coordinates. This gives the rotation  
 matrix combining the `screen` and `R.mat` arguments to `panel.cloud`

`type` character vector, specifying type of cloud plot. Can include one or more of  
 "p", "l", "h" or "b". "p" and "l" mean 'points' and 'lines' respectively,  
 and "b" means 'both'. "h" stands for 'histogram', and causes a line to be  
 drawn from each point to the X-Y plane (i.e., the plane representing  $z = 0$ ), or  
 the lower (or upper) bounding box face, whichever is closer.

`xlim.scaled`, `ylim.scaled`, `zlim.scaled`  
 axis limits (after being scaled to the bounding box)

`zero.scaled` z-axis location (after being scaled to the bounding box) of the X-Y plane in the  
 original data scale, to which lines will be dropped (if within range) from each  
 point when `type = "h"`

`cross` logical, defaults to `TRUE` if `pch = "+"`. `panel.3dscatter` can represent  
 each point by a 3d 'cross' of sorts (it's much easier to understand looking at an  
 example than from a description). This is different from the usual `pch` argu-  
 ment, and reflects the depth of the points and the orientation of the axes. This  
 argument indicates whether this feature will be used.  
 This is useful for two reasons. It can be set to `FALSE` to use "+" as the plotting  
 character in the regular sense. It can also be used to force this feature in grouped  
 displays.

`shade` logical, indicating whether the surface is to be colored using an illumination  
 model with a single light source

`shade.colors.palette`  
 a function (or the name of one) that is supposed to calculate the color of a facet  
 when shading is being used. Three pieces of information are available to the  
 function: first, the cosine of the angle between the incident light ray and the  
 normal to the surface (representing foreshortening); second, the cosine of half  
 the angle between the reflected ray and the viewing direction (useful for non-  
 Lambertian surfaces); and third, the scaled (average) height of that particular  
 facet with respect to the total plot z-axis limits.  
 All three numbers should be between 0 and 1. The  
`shade.colors.palette` function should return a valid color. The  
 default function is obtained from the trellis settings.

`light.source` a 3-vector representing (in cartesian coordinates) the light source. This is rel-  
 ative to the viewing point being (0, 0, 1/distance) (along the positive z-axis),  
 keeping in mind that all observations are bounded within the [-0.5, 0.5] cube

`polynum` quadrilateral faces are drawn in batches of `polynum` at a time. Drawing too few  
 at a time increases the total number of calls to the underlying `grid.polygon`  
 function, which affects speed. Trying to draw too many at once may be unne-  
 cessarily memory intensive. This argument controls the trade-off.

`col.groups` colors for different groups  
`col`, `col.point`, `col.line`, `lty`, `lwd`, `cex`, `pch`, `alpha`  
 graphical parameters  
`...` other parameters, passed down when appropriate

## Details

These functions together are responsible for the content drawn inside each panel in `cloud` and `wireframe`. `panel.wireframe` is a wrapper to `panel.cloud`, which does the actual work.

`panel.cloud` is responsible for drawing the content that does not depend on the data, namely, the bounding box, the arrows/scales, etc. At some point, depending on whether `wireframe` is `TRUE`, it calls either `panel.3d.wireframe` or `panel.3d.cloud`, which draws the data-driven part of the plot.

The arguments accepted by these two functions are different, since they have essentially different purposes. For `cloud`, the data is unstructured, and `x`, `y` and `z` are all passed to the `panel.3d.cloud` function. For `wireframe`, on the other hand, `x` and `y` are increasing vectors with unique values, defining a rectangular grid. `z` must be a matrix with `length(x) * length(y)` rows, and as many columns as the number of groups.

`panel.3dscatter` is the default `panel.3d.cloud` function. It has a `type` argument similar to `panel.xyplot`, and supports grouped displays. It tries to honour depth ordering, i.e., points and lines closer to the camera are drawn later, overplotting more distant ones. (Of course there is no absolute ordering for line segments, so an ad hoc ordering is used. There is no hidden point removal.)

`panel.3dwire` is the default `panel.3d.wireframe` function. It calculates polygons corresponding to the facets one by one, but waits till it has collected information about `plymum` facets, and draws them all at once. This avoids the overhead of drawing `grid.polygon` repeatedly, speeding up the rendering considerably. If `shade = TRUE`, these attempt to color the surface as being illuminated from a light source at `light.source`. `palette.shade` is a simple function that provides the default shading colors

Multiple surfaces are drawn if `groups` is non-null in the call to `wireframe`, however, the algorithm is not sophisticated enough to render intersecting surfaces correctly.

F\_1\_panel.densityplot

*Default Panel Function for densityplot*

---

## Description

This is the default panel function for `densityplot`.

## Usage

```
panel.densityplot(x, darg, plot.points = "jitter", ref = FALSE,
                 groups = NULL, weights = NULL,
                 jitter.amount, type, ...)
```

**Arguments**

<code>x</code>	data points for which density is to be estimated
<code>darg</code>	list of arguments to be passed to the <code>density</code> function. Typically, this should be a list with zero or more of the following components : <code>bw</code> , <code>adjust</code> , <code>kernel</code> , <code>window</code> , <code>width</code> , <code>give.Rkern</code> , <code>n</code> , <code>from</code> , <code>to</code> , <code>cut</code> , <code>na.rm</code> (see <a href="#">density</a> for details)
<code>plot.points</code>	logical specifying whether or not the data points should be plotted along with the estimated density. Alternatively, a character string specifying how the points should be plotted. Meaningful values are <code>"rug"</code> , in which case <a href="#">panel.rug</a> is used to plot a 'rug', and <code>"jitter"</code> , in which case the points are jittered vertically to better distinguish overlapping points.
<code>ref</code>	logical, whether to draw x-axis
<code>groups</code>	an optional grouping variable. If present, <a href="#">panel.superpose</a> will be used instead to display each subgroup
<code>weights</code>	numeric vector of weights for the density calculations. If this is specified, the <code>...</code> part must also include a <code>subscripts</code> argument that matches the weights to <code>x</code> .
<code>jitter.amount</code>	when <code>plot.points="jitter"</code> , the value to use as the <code>amount</code> argument to <a href="#">jitter</a> .
<code>type</code>	<code>type</code> argument used to plot points, if requested. This is not expected to be useful, it is available mostly to protect a <code>type</code> argument, if specified, from affecting the density curve.
<code>...</code>	extra graphical parameters. Note that additional arguments to <a href="#">panel.rug</a> cannot be passed on through <code>panel.densityplot</code> .

F\_1\_panel.dotplot *Default Panel Function for dotplot*

---

**Description**

Default panel function for `dotplot`.

**Usage**

```
panel.dotplot(x, y, horizontal = TRUE,
              pch, col, lty, lwd,
              col.line, levels.fos,
              groups = NULL,
              ...)
```

**Arguments**

<code>x, y</code>	variables to be plotted in the panel. Typically <code>y</code> is the ‘factor’
<code>horizontal</code>	logical. If <code>FALSE</code> , the plot is ‘transposed’ in the sense that the behaviours of <code>x</code> and <code>y</code> are switched. <code>x</code> is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of <code>bwplot</code> for a fuller explanation.
<code>pch, col, lty, lwd, col.line</code>	graphical parameters
<code>levels.fos</code>	locations where reference lines will be drawn
<code>groups</code>	grouping variable (affects graphical parameters)
<code>...</code>	extra parameters, passed to <code>panel.xyplot</code> which is responsible for drawing the foreground points ( <code>panel.dotplot</code> only draws the background reference lines).

**Details**

Creates (possibly grouped) Dotplot of `x` against `y` or vice versa

---

F\_1\_panel.histogram

*Default Panel Function for histogram*

---

**Description**

This is the default panel function for histogram.

**Usage**

```
panel.histogram(x,  
                breaks,  
                equal.widths = TRUE,  
                type = "density",  
                nint = round(log2(length(x)) + 1),  
                alpha, col, border, lty, lwd,  
                ...)
```

**Arguments**

<code>x</code>	The data points for which the histogram is to be drawn
<code>breaks</code>	The breakpoints for the histogram
<code>equal.widths</code>	logical used when <code>breaks==NULL</code>
<code>type</code>	Type of histogram, possible values being "percent", "density" and "count"
<code>nint</code>	Number of bins for the histogram
<code>alpha, col, border, lty, lwd</code>	graphical parameters for bars; defaults are obtained from the <code>plot.polygon</code> settings.
<code>...</code>	other arguments, passed to <code>hist</code> when deemed appropriate

F\_1\_panel.levelplot

*Panel Functions for levelplot and contourplot*

---

**Description**

These are the default panel functions for `levelplot` and `contourplot`. Also documented is an alternative raster-based panel function for use with `levelplot`.

**Usage**

```
panel.levelplot(x, y, z,
               subscripts,
               at = pretty(z),
               shrink,
               labels,
               label.style = c("mixed", "flat", "align"),
               contour = FALSE,
               region = TRUE,
               col = add.line$col,
               lty = add.line$lty,
               lwd = add.line$lwd,
               border = "transparent",
               ...,
               col.regions = regions$col,
               alpha.regions = regions$alpha)
panel.contourplot(...)

panel.levelplot.raster(x, y, z,
```

```

subscripts,
at = pretty(z),
...,
col.regions = regions$col,
alpha.regions = regions$alpha,
interpolate = FALSE)

```

## Arguments

<code>x, y, z</code>	Variables defining the plot.
<code>subscripts</code>	Integer vector indicating what subset of <code>x</code> , <code>y</code> and <code>z</code> to draw.
<code>at</code>	Numeric vector giving breakpoints along the range of <code>z</code> . See <a href="#">levelplot</a> for details.
<code>shrink</code>	Either a numeric vector of length 2 (meant to work as both <code>x</code> and <code>y</code> components), or a list with components <code>x</code> and <code>y</code> which are numeric vectors of length 2. This allows the rectangles to be scaled proportional to the <code>z</code> -value. The specification can be made separately for widths ( <code>x</code> ) and heights ( <code>y</code> ). The elements of the length 2 numeric vector gives the minimum and maximum proportion of shrinkage (corresponding to min and max of <code>z</code> ).
<code>labels</code>	Either a logical scalar indicating whether the labels are to be drawn, or a character or expression vector giving the labels associated with the <code>at</code> values. Alternatively, <code>labels</code> can be a list with the following components: <code>labels</code> : a character or expression vector giving the labels. This can be omitted, in which case the defaults will be used. <code>col, cex, alpha</code> : graphical parameters for label texts <code>fontfamily, fontface, font</code> : font used for the labels
<code>label.style</code>	Controls how label positions and rotation are determined. A value of "flat" causes the label to be positioned where the contour is flattest, and the label is not rotated. A value of "align" causes the label to be drawn as far from the boundaries as possible, and the label is rotated to align with the contour at that point. The default is to mix these approaches, preferring the flattest location unless it is too close to the boundaries.
<code>contour</code>	A logical flag, specifying whether contour lines should be drawn.
<code>region</code>	A logical flag, specifying whether inter-contour regions should be filled with appropriately colored rectangles.
<code>col, lty, lwd</code>	graphical parameters for contour lines
<code>border</code>	border color for rectangles used when <code>region=TRUE</code> .
<code>...</code>	Extra parameters.
<code>col.regions</code>	A vector of colors, or a function to produce a vector of colors, to be used if <code>region=TRUE</code> . Each interval defined by <code>at</code> is assigned a color, so the number of colors actually used is one less than the length of <code>at</code> . See <a href="#">level.colors</a> for details on how the color assignment is done.
<code>alpha.regions</code>	numeric scalar controlling transparency of facets
<code>interpolate</code>	logical, passed to <a href="#">grid.raster</a> .

**Details**

The same panel function is used for both `levelplot` and `contourplot` (which differ only in default values of some arguments). `panel.contourplot` is a simple wrapper to `panel.levelplot`.

When `contour=TRUE`, the `contourLines` function is used to calculate the contour lines.

`panel.levelplot.raster` is an alternative panel function that uses the raster drawing abilities in R 2.11.0 and higher (through `grid.raster`). It has fewer options (e.g., can only render data on an equispaced grid), but can be more efficient.

F\_1\_panel.pairs      *Default Superpanel Function for splom*

---

**Description**

This is the default superpanel function for `splom`.

**Usage**

```
panel.pairs(z,
            panel = lattice.getOption("panel.splom"),
            lower.panel = panel,
            upper.panel = panel,
            diag.panel = "diag.panel.splom",
            as.matrix = FALSE,
            groups = NULL,
            panel.subscripts,
            subscripts,
```

```

pscales = 5,

prepanel.limits = function(x) if (is.factor(x)) levels(x) else
  extend.limits(range(as.numeric(x), finite = TRUE)),

varname.col, varname.cex, varname.font,
varname.fontfamily, varname.fontface,
axis.text.col, axis.text.cex, axis.text.font,
axis.text.fontfamily, axis.text.fontface,
axis.line.col, axis.line.lty, axis.line.lwd,
axis.line.alpha, axis.line.tck,
...)
diag.panel.splom(x = NULL,
  varname = NULL, limits, at = NULL, lab = NULL,
  draw = TRUE,
  varname.col, varname.cex,
  varname.lineheight, varname.font,
  varname.fontfamily, varname.fontface,
  axis.text.col, axis.text.alpha,
  axis.text.cex, axis.text.font,
  axis.text.fontfamily, axis.text.fontface,
  axis.line.col, axis.line.alpha,
  axis.line.lty, axis.line.lwd,
  axis.line.tck,
  ...)

```

## Arguments

<code>z</code>	The data frame used for the plot.
<code>panel</code> , <code>lower.panel</code> , <code>upper.panel</code>	The panel function used to display each pair of variables. If specified, <code>lower.panel</code> and <code>upper.panel</code> are used for panels below and above the diagonal respectively.
<code>diag.panel</code>	The panel function used for the diagonals. See arguments to <code>diag.panel.splom</code> to know what arguments this function is passed when called.
<code>as.matrix</code>	logical. If TRUE, the layout of the panels will have origin on the top left instead of bottom left (similar to <code>pairs</code> ). This is in essence the same functionality as provided by <code>as.table</code> for the panel layout
<code>groups</code>	Grouping variable, if any
<code>panel.subscripts</code>	logical specifying whether the panel function accepts an argument named <code>subscripts</code> .
<code>subscripts</code>	The indices of the rows of <code>z</code> that are to be displayed in this (super)panel.
<code>pscales</code>	Controls axis labels, passed down from <code>splom</code> . If <code>pscales</code> is a single number, it indicates the approximate number of equally-spaced ticks that should appear on each axis. If <code>pscales</code> is a list, it should have one component for each column in <code>z</code> , each of which itself a list with the following valid components: <code>at</code> : a numeric vector specifying tick locations <code>labels</code> : character vector labels to go with <code>at</code>

`limits`: numeric 2-vector specifying axis limits (should be made more flexible at some point to handle factors)

These are specifications on a per-variable basis, and used on all four sides in the diagonal cells used for labelling. Factor variables are labelled with the factor names. Use `pscales=0` to suppress the axes entirely.

`prepanel.limits`

The 'regular' high level lattice plots such as `xyplot` use the `prepanel` function for deciding on axis limits from data. This function serves a similar function, and works on a per-variable basis, by calculating the limits, which can be overridden by the corresponding `limits` component in the `pscales` list.

`x` data vector corresponding to that row / column (which will be the same for diagonal 'panels').

`varname` (scalar) character string or expression that is to be written centred within the panel

`limits` numeric of length 2, or, vector of characters, specifying the scale for that panel (used to calculate tick locations when missing)

`at` locations of tick marks

`lab` optional labels for tick marks

`draw` logical, specifying whether to draw the tick marks and labels. If FALSE, only variable names are written

`varname.col`, `varname.cex`, `varname.lineheight`, `varname.font`, `varname.fontfamily`, graphical parameters for the variable name in each diagonal panel

`axis.text.col`, `axis.text.cex`, `axis.text.font`, `axis.text.fontfamily`, `axis.text.f` graphical parameters for axis tick marks and labels

`axis.line.tck`

length of tick marks in diagonal panels

... extra arguments passed on to `panel`, `lower.panel`, `upper.panel` and `diag.panel` from `panel.pairs`. Currently ignored by `diag.panel.splom`.

## Details

`panel.pairs` is the function that is actually passed in as the `panel` function in a trellis object produced by `splom` (taking the `panel` function as its argument).

Note that the axis labeling does not support date-time classes at present.

F\_1\_panel.parallel *Default Panel Function for parallel*

---

### Description

This is the default panel function for `parallel`.

### Usage

```
panel.parallel(x, y, z, subscripts,
              groups = NULL,
              col, lwd, lty, alpha,
              common.scale = FALSE,
              lower,
              upper,
              ...,
              horizontal.axis = TRUE)
```

### Arguments

<code>x, y</code>	dummy variables, ignored.
<code>z</code>	The data frame used for the plot. Each column will be coerced to numeric before being plotted, and an error will be issued if this fails.
<code>subscripts</code>	The indices of the rows of <code>z</code> that are to be displayed in this panel.
<code>groups</code>	An optional grouping variable. If specified, different groups are distinguished by use of different graphical parameters (i.e., rows of <code>z</code> in the same group share parameters).
<code>col, lwd, lty, alpha</code>	graphical parameters (defaults to the settings for <code>superpose.line</code> ). If <code>groups</code> is non-null, these parameters used one for each group. Otherwise, they are recycled and used to distinguish between rows of the data frame <code>z</code> .
<code>common.scale</code>	logical, whether a common scale should be used columns of <code>z</code> . Defaults to <code>FALSE</code> , in which case the horizontal range for each column is different (as determined by <code>lower</code> and <code>upper</code> ).
<code>lower, upper</code>	numeric vectors replicated to be as long as the number of columns in <code>z</code> . Determines the lower and upper bounds to be used for scaling the corresponding columns of <code>z</code> after coercing them to numeric. Defaults to the minimum and maximum of each column. Alternatively, these could be functions (to be applied on each column) that return a scalar.
<code>...</code>	other arguments (ignored)
<code>horizontal.axis</code>	logical indicating whether the parallel axes should be laid out horizontally ( <code>TRUE</code> ) or vertically ( <code>FALSE</code> ).

### Details

Produces parallel coordinate plots, which are easier to understand from an example than through a verbal description. See example for [parallel](#)

F\_1\_panel.qqmath    *Default Panel and Prepanel Function for qqmath*

---

**Description**

This is the default panel function for qqmath.

**Usage**

```
panel.qqmath(x, f.value = NULL,
             distribution = qnorm,
             qtype = 7,
             groups = NULL, ...,
             tails.n = 0)
```

**Arguments**

x	vector (typically numeric, coerced if not) of data values to be used in the panel.
f.value, distribution	Defines how quantiles are calculated. See <a href="#">qqmath</a> for details.
qtype	The type argument to be used in <a href="#">quantile</a>
groups	An optional grouping variable. Within each panel, one Q-Q plot is produced for every level of this grouping variable, differentiated by different graphical parameters.
...	further arguments, often graphical parameters.
tails.n	number of data points to represent exactly on each tail of the distribution. This reproduces the effect of f.value = NULL for the extreme data values, while approximating the remaining data. It has no effect if f.value = NULL. If tails.n is given, qtype is forced to be 1.

**Details**

Creates a Q-Q plot of the data and the theoretical distribution given by distribution. Note that most of the arguments controlling the display can be supplied directly to the high-level qqmath call.

[qqmath](#)

**Examples**

```
set.seed(0)
xx <- rt(10000, df = 10)
qqmath(~ xx, type = c("b", "g"), pch = "+", distribution = qnorm,
  main = c("raw", "ppoints(100)", "tails.n = 50"),
  panel = function(..., f.value) {
    switch(panel.number(),
      panel.qqmath(..., f.value = NULL),
      panel.qqmath(..., f.value = ppoints(100)),
      panel.qqmath(..., f.value = ppoints(100), tails.n = 50)
    ), layout = c(3, 1))[c(1,1,1)]
```

---

F\_1\_panel.stripplot

*Default Panel Function for stripplot*

---

**Description**

This is the default panel function for `stripplot`. Also see `panel.superpose`

**Usage**

```
panel.stripplot(x, y, jitter.data = FALSE,
  factor = 0.5, amount = NULL,
  horizontal = TRUE, groups = NULL,
  ...)
```

**Arguments**

<code>x, y</code>	coordinates of points to be plotted
<code>jitter.data</code>	whether points should be jittered to avoid overplotting. The actual jittering is performed inside <a href="#">panel.xyplot</a> , using its <code>jitter.x</code> or <code>jitter.y</code> argument (depending on the value of <code>horizontal</code> ).
<code>factor, amount</code>	amount of jittering, see <a href="#">jitter</a>
<code>horizontal</code>	logical. If <code>FALSE</code> , the plot is ‘transposed’ in the sense that the behaviours of <code>x</code> and <code>y</code> are switched. <code>x</code> is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of <a href="#">bwplot</a> for a fuller explanation.
<code>groups</code>	optional grouping variable
<code>...</code>	additional arguments, passed on to <a href="#">panel.xyplot</a>

**Details**

Creates stripplot (one dimensional scatterplot) of  $x$  for each level of  $y$  (or vice versa, depending on the value of `horizontal`)

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

**See Also**

[stripplot](#), [jitter](#)

---

F\_1\_panel.xyplot     *Default Panel Function for xyplot*

---

**Description**

This is the default panel function for `xyplot`. Also see `panel.superpose`. The default panel functions for `splom` and `qq` are essentially the same function.

**Usage**

```
panel.xyplot(x, y, type = "p",
             groups = NULL,
             pch, col, col.line, col.symbol,
             font, fontfamily, fontface,
             lty, cex, fill, lwd,
             horizontal = FALSE, ...,
             jitter.x = FALSE, jitter.y = FALSE,
             factor = 0.5, amount = NULL)
panel.splom(...)
panel.qq(...)
```

**Arguments**

<code>x, y</code>	variables to be plotted in the scatterplot
<code>type</code>	character vector consisting of one or more of the following: "p", "l", "h", "b", "o", "s", "S", "r", "a", "g", "smooth". If <code>type</code> has more than one element, an attempt is made to combine the effect of each of the components. The behaviour if any of the first six are included in <code>type</code> is similar to the effect of <code>type</code> in <code>plot</code> (type "b" is actually the same as "o"). "r" adds a regression line (same as <code>panel.lmline</code> , except for default graphical parameters), and "smooth" adds a lowess fit (same as <code>panel.loess</code> ). "g" adds a reference grid using <code>panel.grid</code> in the background. "a" has the effect of calling <code>panel.linejoin</code> , which can be useful for creating interaction plots. The effect of several of these specifications depend on the value of <code>horizontal</code> . Type "s" (and "S") sorts the values along one of the axes (depending on <code>horizontal</code> ); this is unlike the behavior in <code>plot</code> . For the latter behavior, use <code>type = "s"</code> with <code>panel = panel.points</code> . See <code>example(xyplot)</code> and <code>demo(lattice)</code> for examples.

groups an optional grouping variable. If present, `panel.superpose` will be used instead to display each subgroup

col, col.line, col.symbol default colours are obtained from `plot.symbol` and `plot.line` using `trellis.par.get`.

font, fontface, fontfamily font used when pch is a character

pch, lty, cex, lwd, fill other graphical parameters. `fill` serves the purpose of `bg` in `points` for certain values of pch

... extra arguments, if any, for `panel.xyplot`. In most cases `panel.xyplot` ignores these. For types "r" and "smooth", these are passed on to `panel.lmline` and `panel.loess` respectively.

horizontal logical. Controls orientation for certain type's, e.g. one of "h", "s" or "S".

jitter.x, jitter.y logical, whether the data should be jittered before being plotted.

factor, amount controls amount of jittering.

### Details

Creates scatterplot of  $x$  and  $y$ , with various modifications possible via the `type` argument. `panel.qq` draws a 45 degree line before calling `panel.xyplot`.

Note that most of the arguments controlling the display can be supplied directly to the high-level (e.g. `xyplot`) call.

  })[rep(1, length(types))]

```

---

F\_2\_llines

*Replacements of traditional graphics functions*

---

### Description

These functions are intended to replace common low level traditional graphics functions, primarily for use in panel functions. The originals can not be used (at least not easily) because lattice panel functions need to use grid graphics. Low level drawing functions in grid can be used directly as well, and is often more flexible. These functions are provided for convenience and portability.

### Usage

```

lplot.xy(xy, type, pch, lty, col, cex, lwd,
         font, fontfamily, fontface,
         col.line, col.symbol, alpha, fill,
         origin = 0, ...)

llines(x, ...)
lpoints(x, ...)
ltext(x, ...)

## Default S3 method:
llines(x, y = NULL, type = "l",
       col, alpha, lty, lwd, ...)
## Default S3 method:
lpoints(x, y = NULL, type = "p", col, pch, alpha, fill,
        font, fontfamily, fontface, cex, ...)
## Default S3 method:
ltext(x, y = NULL, labels = seq_along(x),
      col, alpha, cex, srt = 0,
      lineheight, font, fontfamily, fontface,
      adj = c(0.5, 0.5), pos = NULL, offset = 0.5, ...)

lsegments(x0, y0, x1, y1, x2, y2,
          col, alpha, lty, lwd, ...)

```

```

lrect(xleft, ybottom, xright, ytop,
      x = (xleft + xright) / 2,
      y = (ybottom + ytop) / 2,
      width = xright - xleft,
      height = ytop - ybottom,
      col = "transparent",
      border = "black",
      lty = 1, lwd = 1, alpha = 1,
      just = "center",
      hjust = NULL, vjust = NULL,
      ...)
larrow(x0 = NULL, y0 = NULL, x1, y1, x2 = NULL, y2 = NULL,
      angle = 30, code = 2, length = 0.25, unit = "inches",
      ends = switch(code, "first", "last", "both"),
      type = "open",
      col = add.line$col,
      alpha = add.line$alpha,
      lty = add.line$lty,
      lwd = add.line$lwd,
      fill = NULL, ...)
lpolygon(x, y = NULL,
        border = "black", col = "transparent", fill = NULL,
        font, fontface, ...)

panel.lines(...)
panel.points(...)
panel.segments(...)
panel.text(...)
panel.rect(...)
panel.arrows(...)
panel.polygon(...)

```

### Arguments

`x`, `y`, `x0`, `y0`, `x1`, `y1`, `x2`, `y2`, `xy`  
 locations. `x2` and `y2` are available for for S compatibility.

`length`, `unit` determines extent of arrow head. `length` specifies the length in terms of `unit`, which can be any valid grid unit as long as it doesn't need a data argument. `unit` defaults to `inches`, which is the only option in the base version of the function, `arrows`.

`angle`, `code`, `type`, `labels`, `srt`, `adj`, `pos`, `offset`  
 arguments controlling behaviour. See respective base functions for details. For `larrow`s and `panel.larrow`s, `type` is either `"open"` or `"closed"`, indicating the type of arrowhead.

`ends` serves the same function as `code`, using descriptive names rather than integer codes. If specified, this overrides `code`

`col`, `alpha`, `lty`, `lwd`, `fill`, `pch`, `cex`, `lineheight`, `font`, `fontfamily`, `fontface`, `co`  
 graphical parameters. `fill` applies to points when `pch` is in 21:25 and specifies the fill color, similar to the `bg` argument in the base graphics function `points`. For devices that support alpha-transparency, a numeric argument `alpha` between 0 and 1 can controls transparency. Be careful with this, since for devices that do not support alpha-transparency, nothing will be drawn at all

if this is set to anything other than 0. `fill`, `font` and `fontface` are included in `lpolygon` only to ensure that they are not passed down (as `gpar` doesn't like them).

`origin` for `type="h"` or `type="H"`, the value to which lines drop down.  
`xleft`, `ybottom`, `xright`, `ytopy`  
 see [rect](#)  
`width`, `height`, `just`, `hjust`, `vjust`  
 finer control over rectangles, see [grid.rect](#)  
`...` extra arguments, passed on to lower level functions as appropriate.

### Details

These functions are meant to be grid replacements of the corresponding base R graphics functions, to allow existing Trellis code to be used with minimal modification. The functions `panel.*` are essentially identical to the `l*` versions, are recommended for use in new code (as opposed to ported code) as they have more readable names.

See the documentation of the base functions for usage. Not all arguments are always supported. All these correspond to the default methods only.

### Note

There is a new `type="H"` option wherever appropriate, which is similar to `type="h"`, but with horizontal lines.

F\_2\_panel.functions

*Useful Panel Functions*

---

### Description

These are predefined panel functions available in lattice for use in constructing new panel functions (usually on-the-fly).

### Usage

```
panel.abline(a = NULL, b = 0,
             h = NULL, v = NULL,
             reg = NULL, coef = NULL,
             col, col.line, lty, lwd, alpha, type,
             ...,
             reference = FALSE)
panel.refline(...)
```

```

panel.curve(expr, from, to, n = 101,
            curve.type = "l",
            col, lty, lwd, type,
            ...)
panel.rug(x = NULL, y = NULL,
         regular = TRUE,
         start = if (regular) 0 else 0.97,
         end = if (regular) 0.03 else 1,
         x.units = rep("npc", 2),
         y.units = rep("npc", 2),
         col, lty, lwd, alpha,
         ...)
panel.average(x, y, fun = mean, horizontal = TRUE,
             lwd, lty, col, col.line, type,
             ...)
panel.linejoin(x, y, fun = mean, horizontal = TRUE,
              lwd, lty, col, col.line, type,
              ...)

panel.fill(col, border, ...)
panel.grid(h=3, v=3, col, col.line, lty, lwd, ...)
panel.lmline(x, y, ...)
panel.loess(x, y, span = 2/3, degree = 1,
           family = c("symmetric", "gaussian"),
           evaluation = 50,
           lwd, lty, col, col.line, type,
           horizontal = FALSE,
           ...)
panel.mathdensity(dmath = dnorm, args = list(mean=0, sd=1),
                 n = 50, col, col.line, lwd, lty, type,
                 ...)

```

### Arguments

<code>x, y</code>	variables defining the contents of the panel
<code>a, b</code>	Coefficients of the line to be added by <code>panel.abline</code> . <code>a</code> can be a vector of length 2, representing the coefficients of the line to be added, in which case <code>b</code> should be missing. <code>a</code> can also be an appropriate 'regression' object, i.e., an object which has a <code>coef</code> method that returns a length 2 numeric vector. The corresponding line will be plotted. The <code>reg</code> argument will override <code>a</code> if specified.
<code>coef</code>	Coefficients of the line to be added as a length 2 vector
<code>reg</code>	A regression object. The corresponding fitted line will be drawn
<code>h, v</code>	For <code>panel.abline</code> , these are numeric vectors giving locations respectively of horizontal and vertical lines to be added to the plot, in native coordinates. For <code>panel.grid</code> , these usually specify the number of horizontal and vertical reference lines to be added to the plot. Alternatively, they can be negative numbers. <code>h=-1</code> and <code>v=-1</code> are intended to make the grids aligned with the axis

labels. This doesn't always work; all that actually happens is that the locations are chosen using `pretty`, which is also how the label positions are chosen in the most common cases (but not for factor or date-time variables, for instance). `h` and `v` can be negative numbers other than `-1`, in which case `-h` and `-v` (as appropriate) is supplied as the `n` argument to `pretty`.

<code>reference</code>	logical indicating whether the default graphical parameters for <code>panel.abline</code> should be taken from the "reference.line" parameter settings. The default is to take them from the "add.line" settings. The <code>panel.refline</code> function is a wrapper around <code>panel.abline</code> that calls it with <code>reference=TRUE</code> .
<code>expr</code>	expression as a function of <code>x</code> or a function to plot as a curve
<code>n</code>	the number of points to use for drawing the curve
<code>regular</code>	logical indicating whether the 'rug' is to be drawn on the regular side (left / bottom) or not (right / top)
<code>start, end</code>	endpoints of rug segments, in normalized parent coordinates (between 0 and 1). Defaults depend on value of <code>regular</code> , and cover 3% of the panel width and height
<code>x.units, y.units</code>	character vector, replicated to be of length two. Specifies the (grid) units associated with <code>start</code> and <code>end</code> above. <code>x.units</code> and <code>y.units</code> are for the rug on the x-axis and y-axis respectively (and thus are associated with <code>start</code> and <code>end</code> values on the y and x scales respectively).
<code>from, to</code>	optional lower and upper x-limits of curve. If missing, limits of current panel are used
<code>curve.type</code>	type of curve ("p" for points, etc), passed to <code>llines</code>
<code>col, col.line, lty, lwd, alpha, border</code>	graphical parameters
<code>type</code>	Usually ignored by the panel functions documented here; the argument is present only to make sure an explicitly specified <code>type</code> argument (perhaps meant for another function) doesn't affect the display.
<code>span, degree, family, evaluation</code>	arguments to <code>loess.smooth</code> , for which <code>panel.loess</code> is essentially a wrapper.
<code>fun</code>	the function that will be applied to the subset of <code>x(y)</code> determined by the unique values of <code>y(x)</code>
<code>horizontal</code>	logical. If <code>FALSE</code> , the plot is 'transposed' in the sense that the behaviours of <code>x</code> and <code>y</code> are switched. <code>x</code> is now the 'factor'. Interpretation of other arguments change accordingly. See documentation of <code>bwplot</code> for a fuller explanation.
<code>dmath</code>	A vectorized function that produces density values given a numeric vector named <code>x</code> , e.g., <code>dnorm</code>
<code>args</code>	list giving additional arguments to be passed to <code>dmath</code>
<code>...</code>	graphical parameters can be supplied. see function definition for details. Color can usually be specified by <code>col</code> , <code>col.line</code> and <code>col.symbol</code> , the last two overriding the first for lines and points respectively.

## Details

`panel.abline` adds a line of the form  $y=a+bx$  or vertical and/or horizontal lines. Graphical parameters are obtained from the "add.line" settings by default. `panel.refline` is similar, but uses the "reference.line" settings for the defaults.

`panel.grid` draws a reference grid.

`panel.curve` adds a curve, similar to what `curve` does with `add = TRUE`. Graphical parameters for the line are obtained from the `add.line` setting.

`panel.average` treats one of `x` and `y` as a factor (according to the value of `horizontal`), calculates `fun` applied to the subsets of the other variable determined by each unique value of the factor, and joins them by a line. Can be used in conjunction with `panel.xyplot` and more commonly with `panel.superpose` to produce interaction plots. See [xyplot](#) documentation for an example. `panel.linejoin` is an alias for `panel.average` retained for back-compatibility and may go away in future.

`panel.mathdensity` plots a (usually theoretical) probability density function. This can be useful in conjunction with `histogram` and `densityplot` to visually estimate goodness of fit (note, however, that `qqmath` is more suitable for this).

`panel.rug` adds a *rug* representation of the (marginal) data to the panel, much like [rug](#).

`panel.lmline(x, y)` is equivalent to `panel.abline(lm(y~x))`.

F\_2\_panel.qqmathline

*Useful panel function with qqmath*

---

### Description

Useful panel function with `qqmath`. Draws a line passing through the points (usually) determined by the .25 and .75 quantiles of the sample and the theoretical distribution.

### Usage

```
panel.qqmathline(x, y = x,
                 distribution = qnorm,
                 probs = c(0.25, 0.75),
                 qtype = 7,
                 groups = NULL,
                 ...)
```

### Arguments

<code>x</code>	The original sample, possibly reduced to a fewer number of quantiles, as determined by the <code>f.value</code> argument to <code>qqmath</code>
<code>y</code>	an alias for <code>x</code> for backwards compatibility
<code>distribution</code>	quantile function for reference theoretical distribution.
<code>probs</code>	numeric vector of length two, representing probabilities. Corresponding quantile pairs define the line drawn.

qtype	the type of quantile computation used in <a href="#">quantile</a>
groups	optional grouping variable. If non-null, a line will be drawn for each group.
...	other arguments.

F\_2\_panel.smoothScatter

*Lattice panel function analogous to smoothScatter*

---

**Description**

This function allows the user to place `smoothScatter` plots in lattice graphics.

**Usage**

```
panel.smoothScatter(x, y = NULL,
                    nbin = 64, cuts = 255,
                    bandwidth,
                    colramp,
                    nrpoints = 100,
                    transformation = function(x) x^0.25,
                    pch = ".",
                    cex = 1, col="black",
                    range.x,
                    ...,
                    raster = FALSE,
                    subscripts)
```

**Arguments**

x	Numeric vector containing x-values or n by 2 matrix containing x and y values.
y	Numeric vector containing y-values (optional). The length of x must be the same as that of y.
nbin	Numeric vector of length 1 (for both directions) or 2 (for x and y separately) containing the number of equally spaced grid points for the density estimation.
cuts	number of cuts defining the color gradient
bandwidth	Numeric vector: the smoothing bandwidth. If missing, these functions come up with a more or less useful guess. This parameter then gets passed on to the function <a href="#">bkde2D</a> .
colramp	Function accepting an integer n as an argument and returning n colors.

<code>nrpoints</code>	Numeric vector of length 1 giving number of points to be superimposed on the density image. The first <code>nrpoints</code> points from those areas of lowest regional densities will be plotted. Adding points to the plot allows for the identification of outliers. If all points are to be plotted, choose <code>nrpoints = Inf</code> .
<code>transformation</code>	Function that maps the density scale to the color scale.
<code>pch, cex</code>	graphical parameters for the <code>nrpoints</code> “outlying” points shown in the display
<code>range.x</code>	see <a href="#">bkde2D</a> for details.
<code>col</code>	<a href="#">points</a> color parameter
<code>...</code>	Further arguments that are passed on to <a href="#">panel.levelplot</a> .
<code>raster</code>	logical; if TRUE, <a href="#">panel.levelplot.raster</a> is used, making potentially smaller output files.
<code>subscripts</code>	ignored, but necessary for handling of <code>...</code> in certain situations. Likely to be removed in future.

### Details

This replicates the display part of the `smoothScatter` function by replacing standard graphics calls by grid-compatible ones.

### Value

The function is called for its side effects, namely the production of the appropriate plots on a graphics device.

### Author(s)

Deepayan Sarkar <[deepayan.sarkar@r-project.org](mailto:deepayan.sarkar@r-project.org)>

### Examples

```
ddf <- as.data.frame(matrix(rnorm(40000), ncol = 4) + 3 * rnorm(10000))
ddf[, c(2,4)] <- (-ddf[, c(2,4)])
xyplot(V1 ~ V2 + V3, ddf, outer = TRUE,
       panel = panel.smoothScatter, aspect = "iso")
splom(ddf, panel = panel.smoothScatter, nbin = 64, raster = TRUE)
```

---

F\_2\_panel.superpose

*Panel Function for Display Marked by groups*

---

### Description

These are panel functions for Trellis displays useful when a grouping variable is specified for use within panels. The `x` (and `y` where appropriate) variables are plotted with different graphical parameters for each distinct value of the grouping variable.

**Usage**

```

panel.superpose(x, y = NULL, subscripts, groups,
               panel.groups = "panel.xyplot",
               ...,
               col, col.line, col.symbol,
               pch, cex, fill, font,
               fontface, fontfamily,
               lty, lwd, alpha,
               type = "p",
               distribute.type = FALSE)
panel.superpose.2(..., distribute.type = TRUE)

panel.superpose.plain(...,
                     col, col.line, col.symbol,
                     pch, cex, fill, font,
                     fontface, fontfamily,
                     lty, lwd, alpha)

```

**Arguments**

<code>x, y</code>	coordinates of the points to be displayed
<code>panel.groups</code>	the panel function to be used for each group of points. Defaults to <code>panel.xyplot</code> (behaviour in S). To be able to distinguish between different levels of the originating group inside <code>panel.groups</code> , it will be supplied two special arguments called <code>group.number</code> and <code>group.value</code> which will hold the numeric code and factor level corresponding to the current level of <code>groups</code> . No special care needs to be taken when writing a <code>panel.groups</code> function if this feature is not used.
<code>subscripts</code>	subscripts giving indices in original data frame
<code>groups</code>	a grouping variable. Different graphical parameters will be used to plot the subsets of observations given by each distinct value of <code>groups</code> . The default graphical parameters are obtained from <code>superpose.symbol</code> and <code>superpose.line</code> using <code>trellis.par.get</code> wherever appropriate
<code>type</code>	usually a character vector specifying what should be drawn for each group, passed on to the <code>panel.groups</code> function, which must know what to do with it. By default, this is <code>panel.xyplot</code> , whose help page describes the admissible values. The functions <code>panel.superpose</code> and <code>panel.superpose.2</code> differ only in the default value of <code>distribute.type</code> , which controls the way the <code>type</code> argument is interpreted. If <code>distribute.type = FALSE</code> , then the interpretation is the same as for <code>panel.xyplot</code> for each of the unique groups. In other words, if <code>type</code> is a vector, all the individual components are honoured concurrently. If <code>distribute.type = TRUE</code> , <code>type</code> is replicated to be as long as the number of unique values in <code>groups</code> , and one component used for the points corresponding to the each different group. Even in this case, it is possible to request multiple types per group, specifying <code>type</code> as a list, each component being the desired <code>type</code> vector for the corresponding group. If <code>distribute.type = FALSE</code> , any occurrence of "g" in <code>type</code> causes a grid to be drawn, and all such occurrences are removed before <code>type</code> is passed on to <code>panel.groups</code> .

`col`, `col.line`, `col.symbol`, `pch`, `cex`, `fill`, `font`, `fontface`, `fontfamily`, `lty`, `lwd`, graphical parameters, replicated to be as long as the number of groups. These are eventually passed down to `panel.groups`, but as scalars rather than vectors. When `panel.groups` is called for the *i*-th level of groups, the corresponding element of each graphical parameter is passed to it.

... Extra arguments. Passed down to `panel.superpose` from `panel.superpose.2`, and to `panel.groups` from `panel.superpose`.

`distribute.type`  
logical controlling interpretation of the `type` argument.

### Details

`panel.superpose` and `panel.superpose.2` differ essentially in how `type` is interpreted by default. The default behaviour in `panel.superpose` is the opposite of that in S, which is the same as that of `panel.superpose.2`.

`panel.superpose.plain` is the same as `panel.superpose`, except that the default settings for the style arguments are the same for all groups and are taken from the default plot style. It is used in [xyplot.ts](#).

### Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org> (`panel.superpose.2` originally contributed by Neil Klepeis)

### See Also

Different functions when used as `panel.groups` gives different types of plots, for example [panel.xyplot](#), [panel.dotplot](#) and [panel.linejoin](#) (This can be used to produce interaction plots).

See [Lattice](#) for an overview of the package.

---

F\_2\_panel.violin    *Panel Function to create Violin Plots*

---

### Description

This is a panel function that can create a violin plot. It is typically used in a high-level call to `bwplot`.

### Usage

```
panel.violin(x, y, box.ratio = 1, box.width,
             horizontal = TRUE,
             alpha, border, lty, lwd, col,
             varwidth = FALSE,
             bw, adjust, kernel, window,
             width, n = 50, from, to, cut,
             na.rm, ...)
```

**Arguments**

<code>x, y</code>	numeric vector or factor. Violin plots are drawn for each unique value of <code>y</code> ( <code>x</code> ) if <code>horizontal</code> is <code>TRUE</code> ( <code>FALSE</code> )
<code>box.ratio</code>	ratio of the thickness of each violin and inter violin space
<code>box.width</code>	thickness of the violins in absolute units; overrides <code>box.ratio</code> . Useful for specifying thickness when the categorical variable is not a factor, as use of <code>box.ratio</code> alone cannot achieve a thickness greater than 1.
<code>horizontal</code>	logical. If <code>FALSE</code> , the plot is ‘transposed’ in the sense that the behaviours of <code>x</code> and <code>y</code> are switched. <code>x</code> is now the ‘factor’. See documentation of <code>bwplot</code> for a fuller explanation.
<code>alpha, border, lty, lwd, col</code>	graphical parameters controlling the violin. Defaults are taken from the "plot.polygon" settings.
<code>varwidth</code>	logical. If <code>FALSE</code> , the densities are scaled separately for each group, so that the maximum value of the density reaches the limit of the allocated space for each violin (as determined by <code>box.ratio</code> ). If <code>TRUE</code> , densities across violins will have comparable scale.
<code>bw, adjust, kernel, window, width, n, from, to, cut, na.rm</code>	arguments to <code>density</code> , passed on as appropriate
<code>...</code>	arguments passed on to <code>density</code> .

**Details**

Creates Violin plot of `x` for every level of `y`. Note that most arguments controlling the display can be supplied to the high-level (typically `bwplot`) call directly.

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

**See Also**

[bwplot](#), [density](#)

**Examples**

```
bwplot(voice.part ~ height, singer,
       panel = function(..., box.ratio) {
         panel.violin(..., col = "transparent",
                     varwidth = FALSE, box.ratio = box.ratio)
         panel.bwplot(..., fill = NULL, box.ratio = .1)
       } )
```

---

F\_3\_prepanel.default

*Default Prepanel Functions*

---

**Description**

These prepanel functions are used as fallback defaults in various high level plot functions in Lattice. These are rarely useful to normal users but may be helpful in developing new displays.

**Usage**

```
prepanel.default.bwplot(x, y, horizontal, nlevels, origin, stack, ...)
prepanel.default.histogram(x, breaks, equal.widths, type, nint, ...)
prepanel.default.qq(x, y, ...)
prepanel.default.xyplot(x, y, type, subscripts, groups, ...)
prepanel.default.cloud(perspective, distance,
                        xlim, ylim, zlim,
                        screen = list(z = 40, x = -60),
                        R.mat = diag(4),
                        aspect = c(1, 1), panel.aspect = 1,
                        ..., zoom = 0.8)
prepanel.default.levelplot(x, y, subscripts, ...)
prepanel.default.qqmath(x, f.value, distribution, qtype,
                        groups, subscripts, ..., tails.n = 0)
prepanel.default.densityplot(x, darg, groups, weights, subscripts, ...)
prepanel.default.parallel(x, y, z, ..., horizontal.axis)
prepanel.default.splom(z, ...)
```

**Arguments**

<code>x, y</code>	x and y values, numeric or factor
<code>horizontal</code>	logical, applicable when one of the variables is to be treated as categorical (factor or shingle).
<code>horizontal.axis</code>	logical indicating whether the parallel axes should be laid out horizontally (TRUE) or vertically (FALSE).
<code>nlevels</code>	number of levels of such a categorical variable.
<code>origin, stack</code>	for barcharts or the <code>type="h"</code> plot type
<code>breaks, equal.widths, type, nint</code>	details of histogram calculations. <code>type</code> has a different meaning in <code>prepanel.default.xyplot</code> (see <a href="#">panel.xyplot</a> )
<code>groups, subscripts</code>	See <a href="#">xyplot</a> . Whenever appropriate, calculations are done separately for each group and then combined.
<code>weights</code>	numeric vector of weights for the density calculations. If this is specified, it is subsetted by <code>subscripts</code> to match it to <code>x</code> .

perspective, distance, xlim, ylim, zlim, screen, R.mat, aspect, panel.aspect, zoom  
 see [panel.cloud](#)  
 f.value, distribution, tails.n  
 see [panel.qqmath](#)  
 darg list of arguments passed to [density](#)  
 z see [panel.parallel](#) and [panel.pairs](#)  
 qtype type of [quantile](#)  
 ... other arguments, usually ignored

**Value**

A list with components `xlim`, `ylim`, `dx` and `dy`, and possibly `xat` and `yat`, the first two being used to calculate panel axes limits, the last two for banking computations. The form of these components are described in the help page for [xyplot](#).

**Author(s)**

Deepayan Sarkar <[Deepayan.Sarkar@R-project.org](mailto:Deepayan.Sarkar@R-project.org)>

**See Also**

---

F\_3\_prepanel.functions

*Useful Prepanel Function for Lattice*

---

**Description**

These are predefined prepanel functions available in Lattice.

**Usage**

```
prepanel.lmline(x, y, ...)
prepanel.loess(x, y, span, degree, family, evaluation, ...)
prepanel.qqmathline(x, y = x, distribution = qnorm,
                    probs = c(0.25, 0.75), qtype = 7,
                    groups, subscripts,
                    ...)
```

**Arguments**

`x`, `y` x and y values, numeric or factor  
`distribution` quantile function for theoretical distribution. This is automatically passed in when this is used as a prepanel function in `qqmath`.  
`qtype` type of [quantile](#)  
`probs` numeric vector of length two, representing probabilities. If used with `aspect="xy"`, the aspect ratio will be chosen to make the line passing through the corresponding quantile pairs as close to 45 degrees as possible.

```
span, degree, family, evaluation
      arguments controlling the underlying loess smooth
groups, subscripts
      See xyplot. Whenever appropriate, calculations are done separately for each
      group and then combined.
...
      other arguments
```

### Value

usually a list with components `xlim`, `ylim`, `dx` and `dy`, the first two being used to calculate panel axes limits, the last two for banking computations. The form of these components are described under `xyplot`. There are also several prepanel functions that serve as the default for high level functions, see `prepanel.default.xyplot`

### Author(s)

---

G\_axis.default

*Default axis annotation utilities*

---

### Description

Lattice functions provide control over how the plot axes are annotated through a common interface. There are two levels of control. The `xscale.components` and `yscale.components` arguments can be functions that determine tick mark locations and labels given a packet. For more direct control, the `axis` argument can be a function that actually draws the axes. The functions documented here are the defaults for these arguments. They can additionally be used as components of user written replacements.

### Usage

```
xscale.components.default(lim,
                          packet.number = 0,
                          packet.list = NULL,
                          top = TRUE,
                          ...)
yscale.components.default(lim,
                          packet.number = 0,
                          packet.list = NULL,
                          right = TRUE,
                          ...)
axis.default(side = c("top", "bottom", "left", "right"),
            scales, components, as.table,
            labels = c("default", "yes", "no"),
            ticks = c("default", "yes", "no"),
            ...)
```

**Arguments**

<code>lim</code>	the range of the data in that packet (data subset corresponding to a combination of levels of the conditioning variable). The range is not necessarily numeric; e.g. for factors, they could be character vectors representing levels, and for the various date-time representations, they could be vectors of length 2 with the corresponding class.
<code>packet.number</code>	which packet (counted according to the packet order, described in <code>print.trellis</code> ) is being processed. In cases where all panels have the same limits, this function is called only once (rather than once for each packet), in which case this argument will have the value 0.
<code>packet.list</code>	list, as long as the number of packets, giving all the actual packets. Specifically, each component is the list of arguments given to the panel function when and if that packet is drawn in a panel. (This has not yet been implemented.)
<code>top, right</code>	the value of the <code>top</code> and <code>right</code> components of the result, as appropriate. See below for interpretation.
<code>side</code>	on which side the axis is to be drawn. The usual partial matching rules apply.
<code>scales</code>	the appropriate component of the <code>scales</code> argument supplied to the high level function, suitably standardized.
<code>components</code>	list, similar to those produced by <code>xscale.components.default</code> and <code>yscale.components.default</code> .
<code>as.table</code>	the <code>as.table</code> argument in the high level function.
<code>labels</code>	whether labels are to be drawn. By default, the rules determined by <code>scales</code> are used.
<code>ticks</code>	whether labels are to be drawn. By default, the rules determined by <code>scales</code> are used.
<code>...</code>	many other arguments may be supplied, and are passed on to other internal functions.

**Details**

These functions are part of a new API introduced in `lattice 0.14` to provide the user more control over how axis annotation is done. While the API has been designed in anticipation of use that was previously unsupported, the implementation has initially focused on reproducing existing capabilities, rather than test new features. At the time of writing, several features are unimplemented. If you require them, please contact the maintainer.

**Value**

`xscale.components.default` and `yscale.components.default` return a list of the form suitable as the `components` argument of `axis.default`. Valid components in the return value of `xscale.components.default` are:

<code>num.limit</code>	A numeric limit for the box.
<code>bottom</code>	A list with two elements, <code>ticks</code> and <code>labels</code> . <code>ticks</code> must be a list with components <code>at</code> and <code>tick</code> which give the location and lengths of tick marks. <code>tick</code> can be a vector, and will be recycled to be as long as <code>at</code> . <code>labels</code> must be a list with components <code>at</code> , <code>labels</code> , and <code>check.overlap</code> . <code>at</code> and <code>labels</code> give the location and labels of the tick labels; this is usually the same as the location

of the ticks, but is not required to be so. `check.overlap` is a logical flag indicating whether overlapping of labels should be avoided by omitting some of the labels while rendering.

`top` This can be a logical flag; if `TRUE`, `top` is treated as being the same as `bottom`; if `FALSE`, axis annotation for the top axis is omitted. Alternatively, `top` can be a list like `bottom`.

Valid components in the return value of `yscale.components.default` are `left` and `right`. Their interpretations are analogous to (respectively) the `bottom` and `top` components described above.

```

---

G\_banking

*Banking*

---

### Description

Calculates banking slope

### Usage

```
banking(dx, dy)
```

**Arguments**

model	the model/formula to be parsed. This can be in either of two possible forms, one for 2d and one for 3d formulas, determined by the <code>dimension</code> argument. The 2d formulas are of the form $y \sim x \mid g_1 * \dots * g_n$ , and the 3d formulas are of the form $z \sim x * y \mid g_1 * \dots * g_n$ . In the first form, $y$ may be omitted. The conditioning variables $g_1, \dots, g_n$ can be omitted in either case.
data	the environment/dataset where the variables in the formula are evaluated.
dimension	dimension of the model, see above
subset	index for choosing a subset of the data frame
groups	the grouping variable, if present
multiple, outer	logicals, determining how a '+' in the y and x components of the formula are processed. See <a href="#">xyplot</a> for details
subscripts	logical, whether subscripts are to be calculated
drop	logical or list, similar to the <code>drop.unused.levels</code> argument in <a href="#">xyplot</a> , indicating whether unused levels of conditioning factors and data variables that are factors are to be dropped.

**Value**

returns a list with several components, including `left`, `right`, `left.name`, `right.name`, `condition` for 2-D, and `left`, `right.x`, `right.y`, `left.name`, `right.x.name`, `right.y.name`, `condition` for 3-D. Other possible components are `groups`, `subscr`

G\_packet.panel.default

*Associating Packets with Panels*

---

**Description**

When a "trellis" object is plotted, panels are always drawn in an order such that columns vary the fastest, then rows and then pages. An optional function can be specified that determines, given the column, row and page and other relevant information, the packet (if any) which should be used in that panel. The function documented here implements the default behaviour, which is to match panel order with packet order, determined by varying the first conditioning variable the fastest, then the second, and so on. This matching is performed after any reordering and/or permutation of the conditioning variables.

**Usage**

```
packet.panel.default(layout, condlevels, page, row, column,
                    skip, all.pages.skip = TRUE)
```

**Arguments**

`layout`            the `layout` argument in high level functions, suitably standardized.

`condlevels`       a list of levels of conditioning variables, after relevant permutations and/or re-ordering of levels

`page, row, column`       the location of the panel in the coordinate system of pages, rows and columns.

`skip`             the `skip` argument in high level functions

`all.pages.skip`       whether `skip` should be replicated over all pages. If `FALSE`, `skip` will be replicated to be only as long as the number of positions on a page, and that template will be used for all pages.

**Value**

A suitable combination of levels of the conditioning variables in the form of a numeric vector as long as the number of conditioning variables, with each element an integer indexing the levels of the corresponding variable. Specifically, if the return value is `p`, then the `i`-th conditioning variable will have level `condlevels[[i]][p[i]]`.

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

**See Also**

**Examples**

```
packet.panel.page <- function(n)
{
  ## returns a function that when used as the 'packet.panel'
  ## argument in print.trellis plots page number 'n' only
  function(layout, page, ...) {
    stopifnot(layout[3] == 1)
    packet.panel.default(layout = layout, page = n, ...)
  }
}

data(mtcars)
HP <- equal.count(mtcars$hp, 6)
p <-
  xyplot(mpg ~ disp | HP * factor(cyl),
         mtcars, layout = c(0, 6, 1))

print(p, packet.panel = packet.panel.page(1))
print(p, packet.panel = packet.panel.page(2))
```

G\_panel.axis

*Panel Function for Drawing Axis Ticks and Labels***Description**

panel.axis is the function used by lattice to draw axes. It is typically not used by users, except those wishing to create advanced annotation. Keep in mind issues of clipping when trying to use it as part of the panel function. current.panel.limits can be used to retrieve a panel's x and y limits.

**Usage**

```
panel.axis(side = c("bottom", "left", "top", "right"),
           at,
           labels = TRUE,
           draw.labels = TRUE,
           check.overlap = FALSE,
           outside = FALSE,
           ticks = TRUE,
           half = !outside,
           which.half,
           tck = as.numeric(ticks),
           rot = if (is.logical(labels)) 0 else c(90, 0),
           text.col, text.alpha, text.cex, text.font,
           text.fontfamily, text.fontface,
           line.col, line.lty, line.lwd, line.alpha)

current.panel.limits(unit = "native")
```

**Arguments**

side	character string indicating which side axes are to be drawn on. Partial specification is allowed.
at	location of labels
labels	the labels to go along with at. The labels can be a character vector or a vector of expressions. Alternatively, this can be a logical. If TRUE, the labels are derived from at, otherwise, labels are empty.
draw.labels	logical indicating whether labels are to be drawn
check.overlap	logical, whether to check for overlapping of labels. This also has the effect of removing at values that are 'too close' to the limits.
outside	logical, whether to the labels draw outside the panel or inside. Note that outside=TRUE will only have a visible effect if clipping is disabled for the viewport (panel).
ticks	logical, whether to draw the tickmarks
half	logical, whether only half of scales will be drawn for each side
which.half	character string, one of "lower" and "upper". Indicates which half is to be used for tick locations if half=TRUE. Defaults to whatever is suitable for <a href="#">splom</a>

`tck`                numeric scalar, multiplier for tick length. Can be negative.  
`rot`                rotation angles for labels in degrees. Can be a vector of length 2 for x- and y-axes respectively  
`text.col`, `text.alpha`, `text.cex`, `text.font`, `text.fontfamily`, `text.fontface`, `line.`  
                      graphical parameters  
`unit`                which grid `unit` the values should be in

### Details

`panel.axis` can draw axis tick marks inside or outside a panel (more precisely, a grid viewport). It honours the (native) axis scales. Used in `panel.pairs` for `splom`, as well as for all the usual axis drawing by the print method for "trellis" objects. It can also be used to enhance plots 'after the fact' by adding axes.

### Value

`current.panel.limits` returns a list with components `xlim` and `ylim`, which are both numeric vectors of length 2, giving the scales of the current panel (viewport). The values correspond to the unit system specified by `unit`, by default "native".

---

`G_panel.number`

*Accessing Auxiliary Information During Plotting*

---

### Description

Control over lattice plots are provided through a collection of user specifiable functions that perform various tasks during the plotting. Not all information is available to all functions. The functions documented here attempt to provide a consistent interface to access relevant information from within these user specified functions, namely those specified as the `panel`, `strip` and `axis` functions.

### Usage

```

current.row()
current.column()
panel.number()
packet.number()
which.packet()

trellis.currentLayout(which = c("packet", "panel"))
  
```

**Arguments**

`which` whether return value (a matrix) should contain panel numbers or packet numbers, which are usually, but not necessarily, the same (see below for details).

**Value**

`trellis.currentLayout` returns a matrix with as many rows and columns as in the layout of panels in the current plot. Entries in the matrix are integer indices indicating which packet (or panel; see below) occupies that position, with 0 indicating the absence of a panel. `current.row` and `current.column` return integer indices specifying which row and column in the layout are currently active. `panel.number` returns an integer counting which panel is being drawn (starting from 1 for the first panel, a.k.a. the panel order). `packet.number` gives the packet number according to the packet order, which is determined by varying the first conditioning variable the fastest, then the second, and so on. `which.packet` returns the combination of levels of the conditioning variables in the form of a numeric vector as long as the number of conditioning variables, with each element an integer indexing the levels of the corresponding variable.

**Note**

The availability of these functions make redundant some features available in earlier versions of lattice, namely optional arguments called `panel.number` and `packet.number` that were made available to `panel` and `strip`. If you have written such functions, it should be enough to replace instances of `panel.number` and `packet.number` by the corresponding function calls. You should also remove `panel.number` and `packet.number` from the argument list of your function to avoid a warning.

If these accessor functions are not enough for your needs, feel free to contact the maintainer and ask for more.

G\_Rows

*Extract rows from a list*

---

**Description**

Convenience function to extract subset of a list. Usually used in creating keys.

**Usage**

```
Rows(x, which)
```

**Arguments**

`x` list with each member a vector of the same length  
`which` index for members of `x`

**Value**

A list similar to `x`, with each `x[[i]]` replaced by `x[[i]][which]`

G\_utilities.3d      *Utility functions for 3-D plots*

---

**Description**

These are (related to) the default panel functions for `cloud` and `wireframe`.

**Usage**

```
ltransform3dMatrix(screen, R.mat)
ltransform3dto3d(x, R.mat, dist)
```

**Arguments**

<code>x</code>	<code>x</code> can be a numeric matrix with 3 rows for <code>ltransform3dto3d</code>
<code>screen</code>	list, as described in <a href="#">panel.cloud</a>
<code>R.mat</code>	4x4 transformation matrix in homogeneous coordinates
<code>dist</code>	controls transformation to account for perspective viewing

**Details**

`ltransform3dMatrix` and `ltransform3dto3d` are utility functions to help in computation of projections. These functions are used inside the panel functions for `cloud` and `wireframe`. They may be useful in user-defined panel functions as well.

The first function takes a list of the form of the `screen` argument in `cloud` and `wireframe` and a `R.mat`, a 4x4 transformation matrix in homogeneous coordinates, to return a new 4x4 transformation matrix that is the result of applying `R.mat` followed by the rotations in `screen`. The second function applies a 4x4 transformation matrix in homogeneous coordinates to a 3xn matrix representing points in 3-D space, and optionally does some perspective computations. (There has been no testing with non-trivial transformation matrices, and my knowledge of the homogeneous coordinate system is very limited, so there may be bugs here.)

H\_barley

*Yield data from a Minnesota barley trial***Description**

Total yield in bushels per acre for 10 varieties at 6 sites in each of two years.

**Usage**

```
barley
```

**Format**

A data frame with 120 observations on the following 4 variables.

**yield** Yield (averaged across three blocks) in bushels/acre.

**variety** Factor with levels "Svansota", "No. 462", "Manchuria", "No. 475", "Velvet", "Peatland", "Glabron", "No. 457", "Wisconsin No. 38", "Trobi".

**year** Factor with levels 1932, 1931

**site** Factor with 6 levels: "Grand Rapids", "Duluth", "University Farm", "Morris", "Crookston", "Waseca"

**Details**

These data are yields in bushels per acre, of 10 varieties of barley grown in 1/40 acre plots at University Farm, St. Paul, and at the five branch experiment stations located at Waseca, Morris, Crookston, Grand Rapids, and Duluth (all in Minnesota). The varieties were grown in three randomized blocks at each of the six stations during 1931 and 1932, different land being used each year of the test.

Immer et al. (1934) present the data for each Year\*Site\*Variety\*Block. The data here is the average yield across the three blocks.

Immer et al. (1934) refer (once) to the experiment as being conducted in 1930 and 1931, then later refer to it (repeatedly) as being conducted in 1931 and 1932. Later authors have continued the confusion.

Cleveland (1993) suggests that the data for the Morris site may have had the years switched.

**Author(s)**

Documentation contributed by Kevin Wright.

H\_environmental      *Atmospheric environmental conditions in New York City*

---

**Description**

Daily measurements of ozone concentration, wind speed, temperature and solar radiation in New York City from May to September of 1973.

**Usage**

```
environmental
```

**Format**

A data frame with 111 observations on the following 4 variables.

**ozone** Average ozone concentration (of hourly measurements) of in parts per billion.

**radiation** Solar radiation (from 08:00 to 12:00) in langleys.

**temperature** Maximum daily emperature in degrees Fahrenheit.

**wind** Average wind speed (at 07:00 and 10:00) in miles per hour.

H\_ethanol

*Engine exhaust fumes from burning ethanol*

---

**Description**

Ethanol fuel was burned in a single-cylinder engine. For various settings of the engine compression and equivalence ratio, the emissions of nitrogen oxides were recorded.

**Usage**

```
ethanol
```

**Format**

A data frame with 88 observations on the following 3 variables.

**NOx** Concentration of nitrogen oxides (NO and NO<sub>2</sub>) in micrograms/J.

**C** Compression ratio of the engine.

**E** Equivalence ratio—a measure of the richness of the air and ethanol fuel mixture.

**Author(s)**

Documentation contributed by Kevin Wright.

H\_melanoma

*Melanoma skin cancer incidence*

---

**Description**

These data from the Connecticut Tumor Registry present age-adjusted numbers of melanoma skin-cancer incidences per 100,000 people in Connecticut for the years from 1936 to 1972.

**Usage**

melanoma

**Format**

A data frame with 37 observations on the following 2 variables.

**year** Years 1936 to 1972.

**incidence** Rate of melanoma cancer per 100,000 population.

**Note**

This dataset is not related to the `melanoma` dataset in the `boot` package with the same name.

The S-PLUS 6.2 help for the melanoma data says that the incidence rate is per *million*, but this is not consistent with data found at the National Cancer Institute (<http://www.nci.nih.gov>).

**Author(s)**

Documentation contributed by Kevin Wright.

**Source**

**References**

Cleveland, William S. (1993). *Visualizing Data*. Hobart Press, Summit, New Jersey.

**Examples**

```
# Time-series plot. Figure 3.64 from Cleveland.
xyplot(incidence ~ year,
       data = melanoma,
       aspect = "xy",
       panel = function(x, y)
         panel.xyplot(x, y, type="o", pch = 16),
       ylim = c(0, 6),
       xlab = "Year",
       ylab = "Incidence")
```

---

H\_singer

*Heights of New York Choral Society singers*

---

**Description**

Heights in inches of the singers in the New York Choral Society in 1979. The data are grouped according to voice part. The vocal range for each voice part increases in pitch according to the following order: Bass 2, Bass 1, Tenor 2, Tenor 1, Alto 2, Alto 1, Soprano 2, Soprano 1.

**Usage**

`singer`

**Format**

A data frame with 235 observations on the following 2 variables.

**height** Height in inches of the singers.

**voice.part** (Unordered) factor with levels "Bass 2", "Bass 1", "Tenor 2", "Tenor 1", "Alto 2", "Alto 1", "Soprano 2", "Soprano 1".

**Author(s)**

Documentation contributed by Kevin Wright.

**Source**

Chambers, J.M., W. S. Cleveland, B. Kleiner, and P. A. Tukey. (1983). *Graphical Methods for Data Analysis*. Chapman and Hall, New York.

**References**

Cleveland, William S. (1993). *Visualizing Data*. Hobart Press, Summit, New Jersey.

**Examples**

```
# Separate histogram for each voice part (Figure 1.2 from Cleveland)
histogram(~ height | voice.part,
          data = singer,
          aspect=1,
          layout = c(2, 4),
          nint=15,
          xlab = "Height (inches)")

# Quantile-Quantile plot (Figure 2.11 from Cleveland)
qqmath(~ height | voice.part,
       data=singer,
       aspect=1,
       layout=c(2,4),
       prepanel = prepanel.qqmathline,
       panel = function(x, ...) {
         panel.grid()
         panel.qqmathline(x, ...)
         panel.qqmath(x, ...)
       },
       xlab = "Unit Normal Quantile",
       ylab="Height (inches)")
```

---

I\_lset

---

*Interface to modify Trellis Settings - Deprecated*

---

**Description**

A (hopefully) simpler alternative to `trellis.par.get/set`. This is deprecated, and the same functionality is now available with `trellis.par.set`

**Usage**

```
lset(theme = col.whitebg())
```

**Arguments**

`theme` a list describing how to change the settings of the current active device. Valid components are those in the list returned by `trellis.par.get()`. Each component must itself be a list, with one or more of the appropriate components (need not have all components). Changes are made to the settings for the currently active device only.

## Chapter 18

# The mgcv package

---

mgcv-package

*GAMs with GCV/AIC/REML smoothness estimation and GAMMs by REML/PQL*

---

### Description

mgcv provides functions for generalized additive modelling ([gam](#) and [bam](#)) and generalized additive mixed modelling ([gamm](#), and [random.effects](#)). The term GAM is taken to include any GLM estimated by quadratically penalized (possibly quasi-) likelihood maximization.

Particular features of the package are facilities for automatic smoothness selection, and the provision of a variety of smooths of more than one variable. User defined smooths can be added. A Bayesian approach to confidence/credible interval calculation is provided. Linear functionals of smooths, penalization of parametric model terms and linkage of smoothing parameters are all supported. Lower level routines for generalized ridge regression and penalized linearly constrained least squares are also available.

### Details

mgcv provides generalized additive modelling functions [gam](#), [predict.gam](#) and [plot.gam](#), which are very similar in use to the S functions of the same name designed by Trevor Hastie (with some extensions). However the underlying representation and estimation of the models is based on a penalized regression spline approach, with automatic smoothness selection. A number of other functions such as [summary.gam](#) and [anova.gam](#) are also provided, for extracting information from a fitted [gamObject](#).

Use of [gam](#) is much like use of [glm](#), except that within a [gam](#) model formula, isotropic smooths of any number of predictors can be specified using [s](#) terms, while scale invariant smooths of any number of predictors can be specified using [te](#) terms. [smooth.terms](#) provides an overview of the built in smooth classes, and [random.effects](#) should be referred to for an overview of random effects terms. Estimation is by penalized likelihood or quasi-likelihood maximization, with smoothness selection by GCV, GACV, gAIC/UBRE or (RE)ML. See [gam](#), [gam.models](#), [linear.functional.terms](#) and [gam.selection](#) for some discussion of model specification and selection. For detailed control of fitting see [gam.convergence](#), [gam](#) arguments [method](#) and [optimizer](#) and [gam.control](#). For checking and visualization see [gam.check](#), [choose.k](#), [vis.gam](#) and [plot.gam](#). While a number of types of smoother are built into the package, it is also extendable with user defined smooths, see [smooth.construct](#), for example.

A Bayesian approach to smooth modelling is used to derive standard errors on predictions, and hence credible intervals. The Bayesian covariance matrix for the model coefficients is returned in `Vp` of the `gamObject`. See `predict.gam` for examples of how this can be used to obtain credible regions for any quantity derived from the fitted model, either directly, or by direct simulation from the posterior distribution of the model coefficients. Approximate p-values can also be obtained for testing individual smooth terms for equality to the zero function, using similar ideas. Frequentist approximations can be used for hypothesis testing based model comparison. See `anova.gam` and `summary.gam` for more on hypothesis testing.

For large datasets (that is large `n`) see `bam` which is a version of `gam` with a much reduced memory footprint.

The package also provides a generalized additive mixed modelling function, `gamm`, based on a PQL approach and `lme` from the `nlme` library (for an `lme4` based version, see package `gamm4`). `gamm` is particularly useful for modelling correlated data (i.e. where a simple independence model for the residual variation is inappropriate). In addition, low level routine `magic` can fit models to data with a known correlation structure.

Some underlying GAM fitting methods are available as low level fitting functions: see `magic` and `mgcv`. But there is little functionality that can not be more conveniently accessed via `gam`. Penalized weighted least squares with linear equality and inequality constraints is provided by `pcls`.

For a complete list of functions type `library(help=mgcv)`.

### Examples

```
## see examples for gam and gamm
```

---

anova.gam

*Approximate hypothesis tests related to GAM fits*

---

### Description

Performs hypothesis tests relating to one or more fitted `gam` objects. For a single fitted `gam` object, Wald tests of the significance of each parametric and smooth term are performed. Otherwise the fitted models are compared using an analysis of deviance table. The tests are usually approximate, unless the models are un-penalized. Simulation evidence suggests that best p-value performance results from using ML estimated smoothing parameters.

**Usage**

```
## S3 method for class 'gam':
anova(object, ..., dispersion = NULL, test = NULL,
       alpha = 0, freq = FALSE)
## S3 method for class 'anova.gam':
print(x, digits = max(3, getOption("digits") - 3), ...)
```

**Arguments**

<code>object, ...</code>	fitted model objects of class <code>gam</code> as produced by <code>gam()</code> .
<code>x</code>	an <code>anova.gam</code> object produced by a single model call to <code>anova.gam()</code> .
<code>dispersion</code>	a value for the dispersion parameter: not normally used.
<code>test</code>	what sort of test to perform for a multi-model call. One of "Chisq", "F" or "Cp".
<code>alpha</code>	adjustment to degrees of freedom per estimated smoothing parameter for a term when called with a single model object. See <a href="#">summary.gam</a> for details.
<code>freq</code>	whether to use frequentist or Bayesian approximations for single smooth term p-values. See <a href="#">summary.gam</a> for details.
<code>digits</code>	number of digits to use when printing output.

**Details**

If more than one fitted model is provided than `anova.glm` is used. If only one model is provided then the significance of each model term is assessed using Wald tests: see [summary.gam](#) for details of the actual computations. In the latter case `print.anova.gam` is used as the printing method. Note that the p-values for smooth terms are approximate only: simulation evidence suggests that they work best with REML or ML smoothness selection.

**Value**

In the multi-model case `anova.gam` produces output identical to [anova.glm](#), which it in fact uses.

In the single model case an object of class `anova.gam` is produced, which is in fact an object returned from [summary.gam](#).

`print.anova.gam` simply produces tabulated output.

**WARNING**

P-values for smooth terms are only approximate.

**Author(s)**

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)> with substantial improvements by Henric Nilsson.

**See Also**

[gam](#), [predict.gam](#), [gam.check](#), [summary.gam](#)

**Examples**

```
library(mgcv)
set.seed(0)
dat <- gamSim(5, n=200, scale=2)

b<-gam(y ~ x0 + s(x1) + s(x2) + s(x3), data=dat)
anova(b)
b1<-gam(y ~ x0 + s(x1) + s(x2), data=dat)
anova(b, b1, test="F")
```

bam

*Generalized additive models for very large datasets***Description**

Fits a generalized additive model (GAM) to a very large data set, the term ‘GAM’ being taken to include any quadratically penalized GLM. The degree of smoothness of model terms is estimated as part of fitting. In use the function is much like `gam`, except that the numerical methods are designed for datasets containing upwards of several tens of thousands of data. The advantage of `bam` is much lower memory footprint than `gam`, but it can also be much faster, for large datasets.

**Usage**

```
bam(formula, family=gaussian(), data=list(), weights=NULL, subset=NULL,
    na.action=na.omit, offset=NULL, method="REML", control=gam.control(),
    scale=0, gamma=1, knots=NULL, sp=NULL, min.sp=NULL, paraPen=NULL,
    chunk.size=10000, ...)
```

**Arguments**

<code>formula</code>	A GAM formula (see <code>formula.gam</code> and also <code>gam.models</code> ). This is exactly like the formula for a GLM except that smooth terms, <code>s</code> and <code>te</code> can be added to the right hand side to specify that the linear predictor depends on smooth functions of predictors (or linear functionals of these).
<code>family</code>	This is a family object specifying the distribution and link to use in fitting etc. See <code>glm</code> and <code>family</code> for more details. A negative binomial family is provided: see <code>negbin</code> , but only the known theta case is supported by <code>bam</code> .
<code>data</code>	A data frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from <code>environment(formula)</code> : typically the environment from which <code>gam</code> is called.
<code>weights</code>	prior weights on the data.
<code>subset</code>	an optional vector specifying a subset of observations to be used in the fitting process.
<code>na.action</code>	a function which indicates what should happen when the data contain ‘NA’s. The default is set by the ‘na.action’ setting of ‘options’, and is ‘na.fail’ if that is unset. The “factory-fresh” default is ‘na.omit’.
<code>offset</code>	Can be used to supply a model offset for use in fitting. Note that this offset will always be completely ignored when predicting, unlike an offset included in <code>formula</code> : this conforms to the behaviour of <code>lm</code> and <code>glm</code> .

method	The smoothing parameter estimation method. "GCV.Cp" to use GCV for unknown scale parameter and Mallows' Cp/UBRE/AIC for known scale. "GACV.Cp" is equivalent, but using GACV in place of GCV. "REML" for REML estimation, including of unknown scale, "P-REML" for REML estimation, but using a Pearson estimate of the scale. "ML" and "P-ML" are similar, but using maximum likelihood in place of REML.
control	A list of fit control parameters returned by <code>gam.control</code> .
scale	If this is positive then it is taken as the known scale parameter. Negative signals that the scale parameter is unknown. 0 signals that the scale parameter is 1 for Poisson and binomial and unknown otherwise. Note that (RE)ML methods can only work with scale parameter 1 for the Poisson and binomial cases.
gamma	It is sometimes useful to inflate the model degrees of freedom in the GCV or UBRE/AIC score by a constant multiplier. This allows such a multiplier to be supplied.
knots	this is an optional list containing user specified knot values to be used for basis construction. For most bases the user simply supplies the knots to be used, which must match up with the <code>k</code> value supplied (note that the number of knots is not always just <code>k</code> ). See <code>tprs</code> for what happens in the " <code>t<sub>p</sub></code> " / " <code>t<sub>s</sub></code> " case. Different terms can use different numbers of knots, unless they share a covariate.
sp	A vector of smoothing parameters can be provided here. Smoothing parameters must be supplied in the order that the smooth terms appear in the model formula. Negative elements indicate that the parameter should be estimated, and hence a mixture of fixed and estimated parameters is possible. If smooths share smoothing parameters then <code>length(sp)</code> must correspond to the number of underlying smoothing parameters.
min.sp	Lower bounds can be supplied for the smoothing parameters. Note that if this option is used then the smoothing parameters <code>full.sp</code> , in the returned object, will need to be added to what is supplied here to get the smoothing parameters actually multiplying the penalties. <code>length(min.sp)</code> should always be the same as the total number of penalties (so it may be longer than <code>sp</code> , if smooths share smoothing parameters).
paraPen	optional list specifying any penalties to be applied to parametric model terms. <code>gam.models</code> explains more.
chunk.size	The model matrix is created in chunks of this size, rather than ever being formed whole.
...	further arguments for passing on e.g. to <code>gam.fit</code> (such as <code>mustart</code> ).

## Details

`bam` operates by first setting up the basis characteristics for the smooths, using a representative subsample of the data. Then the model matrix is constructed in blocks using `predict.gam`. For each block the factor `R`, from the QR decomposition of the whole model matrix is updated, along with `Q'y` and the sum of squares of `y`. At the end of block processing, fitting takes place, without the need to ever form the whole model matrix.

In the generalized case, the same trick is used with the weighted model matrix and weighted pseudodata, at each step of the PIRLS. Smoothness selection is performed on the working model at each stage (performance oriented iteration), to maintain the small memory footprint. This is easy to justify in the case of GCV or Cp/UBRE/AIC based model selection, and also for REML/ML with known scale parameter. It is slightly less well justified in the REML/ML unknown scale parameter case, but it seems unlikely that this case actually behaves any less well.

Note that POI is not as stable as the default nested iteration used with `gam`, but that for very large, information rich, datasets, this is unlikely to matter much.

Note that it is possible to spend most of the computational time on basis evaluation, if an expensive basis is used. In practice this means that the default "tp" basis should be avoided: almost any other basis (e.g. "cr" or "ps") can be used in the 1D case, and tensor product smooths (te) are typically much less costly in the multi-dimensional case.

### Value

An object of class "gam" as described in `gamObject`.

### WARNINGS

The routine will be slow if the default "tp" basis is used.

You must have more unique combinations of covariates than the model has total parameters. (Total parameters is sum of basis dimensions plus sum of non-spline terms less the number of spline terms).

This routine is less stable than 'gam' for a the same dataset.

The negbin family is only supported for the \*known theta\* case.

b1<-bam(y ~ s(x0, bs=bs, k=k) + s(x1, bs=bs, k=k) + s(x2, bs=bs, k=k) +
        s(x3, bs=bs, k=k), data=dat, method="ML", family=poisson())
b1
```

bam.update

*Update a strictly additive bam model for new data.***Description**

Strictly additive models fitted by `bam` can be efficiently updated as new data becomes available, by simply updating the QR decomposition on which estimation is based, and re-optimizing the smoothing parameters, starting from the previous estimates. This routine implements this.

**Usage**

```
bam.update(b, data, chunk.size=10000)
```

**Arguments**

<code>b</code>	A gam object fitted by <code>bam</code> and representing a strictly additive model (i.e. gaussian errors, identity link).
<code>data</code>	Extra data to augment the original data used to obtain <code>b</code> . Must include a column of weights if the original fit was weighted.
<code>chunk.size</code>	size of subsets of data to process in one go when getting fitted values.

**Details**

`bam.update` updates the QR decomposition of the (weighted) model matrix of the GAM represented by `b` to take account of the new data. The orthogonal factor multiplied by the response vector is also updated. Given these updates the model and smoothing parameters can be re-estimated, as if the whole dataset (original and the new data) had been fitted in one go.

Note that there may be small numerical differences in fit between fitting the data all at once, and fitting in stages by updating, if the smoothing bases used have any of their details set with reference to the data (e.g. default knot locations).

**Value**

An object of class "gam" as described in `gamObject`.

choose.k

*Basis dimension choice for smooths*

---

**Description**

Choosing the basis dimension, and checking the choice, when using penalized regression smoothers.

Penalized regression smoothers gain computational efficiency by virtue of being defined using a basis of relatively modest size,  $k$ . When setting up models in the `mgcv` package, using `s` or `te` terms in a model formula,  $k$  must be chosen: the defaults are essentially arbitrary.

In practice  $k-1$  (or  $k$ ) sets the upper limit on the degrees of freedom associated with an `s` smooth (1 degree of freedom is usually lost to the identifiability constraint on the smooth). For `te` smooths the upper limit of the degrees of freedom is given by the product of the  $k$  values provided for each marginal smooth less one, for the constraint. However the actual effective degrees of freedom are controlled by the degree of penalization selected during fitting, by GCV, AIC, REML or whatever is specified. The exception to this is if a smooth is specified using the `fx=TRUE` option, in which case it is unpenalized.

So, exact choice of  $k$  is not generally critical: it should be chosen to be large enough that you are reasonably sure of having enough degrees of freedom to represent the underlying ‘truth’ reasonably well, but small enough to maintain reasonable computational efficiency. Clearly ‘large’ and ‘small’ are dependent on the particular problem being addressed.

As with all model assumptions, it is useful to be able to check the choice of  $k$  informally. If the effective degrees of freedom for a model term are estimated to be much less than  $k-1$  then this is unlikely to be very worthwhile, but as the EDF approach  $k-1$ , checking can be important. A useful general purpose approach goes as follows: (i) fit your model and extract the deviance residuals; (ii) for each smooth term in your model, fit an equivalent, single, smooth to the residuals, using a substantially increased  $k$  to see if there is pattern in the residuals that could potentially be explained by increasing  $k$ . Examples are provided below.

The obvious, but more costly, alternative is simply to increase the suspect  $k$  and refit the original model. If there are no statistically important changes as a result of doing this, then  $k$  was large enough. (Change in the smoothness selection criterion, and/or the effective degrees of freedom, when  $k$  is increased, provide the obvious numerical measures for whether the fit has changed substantially.)

One scenario that can cause confusion is this: a model is fitted with  $k=10$  for a smooth term, and the EDF for the term is estimated as 7.6, some way below the maximum of 9. The model is then refitted with  $k=20$  and the EDF increases to 8.7 - what is happening - how come the EDF was not 8.7 the first time around? The explanation is that the function space with  $k=20$  contains a larger subspace of functions with EDF 8.7 than did the function space with  $k=10$ : one of the functions in this larger subspace fits the data a little better than did any function in the smaller subspace. These subtleties seldom have much impact on the statistical conclusions to be drawn from a model fit, however.

### Examples

```
## Simulate some data ....
library(mgcv)
set.seed(0)
dat <- gamSim(1,n=400,scale=2)

## fit a GAM with quite low `k`
b<-gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=6)+s(x3,k=6),data=dat)
plot(b,pages=1)

## Economical tactic (see below for more obvious approach)....
## check for residual pattern, removeable by increasing `k`
## typically `k`, below, should be substantially larger than
## the original, `k` but certainly less than n/2.
## Note use of cheap "cs" shrinkage smoothers, and gamma=1.4
## to reduce chance of overfitting...
rsd <- residuals(b)
gam(rsd~s(x0,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
gam(rsd~s(x1,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
gam(rsd~s(x2,k=40,bs="cs"),gamma=1.4,data=dat) ## `k` too low
gam(rsd~s(x3,k=40,bs="cs"),gamma=1.4,data=dat) ## fine

## similar example with multi-dimensional smooth
```

```

b1 <- gam(y~s(x0)+s(x1,x2,k=15)+s(x3),data=dat)
rsd <- residuals(b1)
gam(rsd~s(x0,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
gam(rsd~s(x1,x2,k=100,bs="ts"),gamma=1.4,data=dat) ## `k' too low
gam(rsd~s(x3,k=40,bs="cs"),gamma=1.4,data=dat) ## fine

## and a `te' example
b2 <- gam(y~s(x0)+te(x1,x2,k=4)+s(x3),data=dat)
rsd <- residuals(b2)
gam(rsd~s(x0,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
gam(rsd~te(x1,x2,k=10,bs="cs"),gamma=1.4,data=dat) ## `k' too low
gam(rsd~s(x3,k=40,bs="cs"),gamma=1.4,data=dat) ## fine

## same approach works with other families in the original model
dat <- gamSim(1,n=400,scale=.25,dist="poisson")
bp<-gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=6)+s(x3,k=6),
        family=poisson,data=dat)
rsd <- residuals(bp)
gam(rsd~s(x0,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
gam(rsd~s(x1,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
gam(rsd~s(x2,k=40,bs="cs"),gamma=1.4,data=dat) ## `k' too low
gam(rsd~s(x3,k=40,bs="cs"),gamma=1.4,data=dat) ## fine

rm(dat)

## More obvious, but more expensive tactic... Just increase
## suspicious k until fit is stable.

set.seed(0)
dat <- gamSim(1,n=400,scale=2)
## fit a GAM with quite low `k'
b <- gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=6)+s(x3,k=6),
        data=dat,method="REML")
b
## edf for 3rd smooth is highest as proportion of k -- increase k
b <- gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=12)+s(x3,k=6),
        data=dat,method="REML")
b
## edf substantially up, -ve REML substantially down
b <- gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=24)+s(x3,k=6),
        data=dat,method="REML")
b
## slight edf increase and -ve REML change
b <- gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=40)+s(x3,k=6),
        data=dat,method="REML")
b
## definitely stabilized (but really k around 20 would have been fine)

```

---

cSplineDes

*Evaluate cyclic B spline basis*

---

### Description

Uses `splineDesign` to set up the model matrix for a cyclic B-spline basis.

**Usage**

```
cSplineDes(x, knots, ord = 4)
```

**Arguments**

x	covariate values for smooth.
knots	The knot locations: the range of these must include all the data.
ord	order of the basis. 4 is a cubic spline basis. Must be >1.

**Details**

The routine is a wrapper that sets up a B-spline basis, where the basis functions wrap at the first and last knot locations.

**Value**

A matrix with `length(x)` rows and `length(knots)-1` columns.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**See Also**

[cyclic.p.spline](#)

**Examples**

```
## create some x's and knots...
n <- 200
x <- 0:(n-1)/(n-1);k<- 0:5/5
X <- cSplineDes(x,k) ## cyclic spline design matrix
## plot evaluated basis functions...
plot(x,X[,1],type="l"); for (i in 2:5) lines(x,X[,i],col=i)
## check that the ends match up....
ee <- X[1,]-X[n,];ee
tol <- .Machine$double.eps^.75
if (all.equal(ee,ee*0,tol=tol)!=TRUE)
  stop("cyclic spline ends don't match!")

## similar with uneven data spacing...
x <- sort(runif(n)) + 1 ## sorting just makes end checking easy
k <- seq(min(x),max(x),length=8) ## create knots
X <- cSplineDes(x,k) ## get cyclic spline model matrix
plot(x,X[,1],type="l"); for (i in 2:ncol(X)) lines(x,X[,i],col=i)
ee <- X[1,]-X[n,];ee ## do ends match??
tol <- .Machine$double.eps^.75
if (all.equal(ee,ee*0,tol=tol)!=TRUE)
  stop("cyclic spline ends don't match!")
```

---

`exclude.too.far`      *Exclude prediction grid points too far from data*

---

### Description

Takes two arrays defining the nodes of a grid over a 2D covariate space and two arrays defining the location of data in that space, and returns a logical vector with elements `TRUE` if the corresponding node is too far from data and `FALSE` otherwise. Basically a service routine for `vis.gam` and `plot.gam`.

### Usage

```
exclude.too.far(g1, g2, d1, d2, dist)
```

### Arguments

<code>g1</code>	co-ordinates of grid relative to first axis.
<code>g2</code>	co-ordinates of grid relative to second axis.
<code>d1</code>	co-ordinates of data relative to first axis.
<code>d2</code>	co-ordinates of data relative to second axis.
<code>dist</code>	how far away counts as too far. Grid and data are first scaled so that the grid lies exactly in the unit square, and <code>dist</code> is a distance within this unit square.

### Details

Linear scalings of the axes are first determined so that the grid defined by the nodes in `g1` and `g2` lies exactly in the unit square (i.e. on  $[0,1]$  by  $[0,1]$ ). These scalings are applied to `g1`, `g2`, `d1` and `d2`. The minimum Euclidean distance from each node to a datum is then determined and if it is greater than `dist` the corresponding entry in the returned array is set to `TRUE` (otherwise to `FALSE`). The distance calculations are performed in compiled code for speed without storage overheads.

### Value

A logical array with `TRUE` indicating a node in the grid defined by `g1`, `g2` that is ‘too far’ from any datum.

### Author(s)

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

```

---

extract.lme.cov	<i>Extract the data covariance matrix from an lme object</i>
-----------------	--

---

**Description**

This is a service routine for [gamm](#). Extracts the estimated covariance matrix of the data from an `lme` object, allowing the user control about which levels of random effects to include in this calculation. `extract.lme.cov` forms the full matrix explicitly: `extract.lme.cov2` tries to be more economical than this.

**Usage**

```
extract.lme.cov(b, data, start.level=1)
extract.lme.cov2(b, data, start.level=1)
```

**Arguments**

<code>b</code>	A fitted model object returned by a call to <a href="#">lme</a> .
<code>data</code>	The data frame/ model frame that was supplied to <a href="#">lme</a> .
<code>start.level</code>	The level of nesting at which to start including random effects in the calculation. This is used to allow smooth terms to be estimated as random effects, but treated like fixed effects for variance calculations.

**Details**

The random effects, correlation structure and variance structure used for a linear mixed model combine to imply a covariance matrix for the response data being modelled. These routines extract that covariance matrix. The process is slightly complicated, because different components of the fitted model object are stored in different orders (see function code for details!).

The `extract.lme.cov` calculation is not optimally efficient, since it forms the full matrix, which may in fact be sparse. `extract.lme.cov2` is more efficient. If the covariance matrix is diagonal, then only the leading diagonal is returned; if it can be written as a block diagonal matrix (under some permutation of the original data) then a list of matrices defining the non-zero blocks is returned along with an index indicating which row of the original data each row/column of the block diagonal matrix relates to. The block sizes are defined by the coarsest level of grouping in the random effect structure.

[gamm](#) uses `extract.lme.cov2`.

`extract.lme.cov` does not currently deal with the situation in which the grouping factors for a correlation structure are finer than those for the random effects. `extract.lme.cov2` does deal with this situation.

**Value**

For `extract.lme.cov` an estimated covariance matrix.

For `extract.lme.cov2` a list containing the estimated covariance matrix and an indexing array. The covariance matrix is stored as the elements on the leading diagonal, a list of the matrices defining a block diagonal matrix, or a full matrix if the previous two options are not possible.

fix.family.link      *Modify families for use in GAM fitting*

---

**Description**

Generalized Additive Model fitting by ‘outer’ iteration, requires extra derivatives of the variance and link functions to be added to family objects. The functions add what is needed.

**Usage**

```
fix.family.link(fam)
fix.family.var(fam)
fix.family.ls(fam)
```

**Arguments**

fam                      A family.

## Details

Outer iteration GAM estimation requires derivatives of the GCV, UBRE/gAIC, GACV, REML or ML score, which are obtained by finding the derivatives of the model coefficients w.r.t. the log smoothing parameters, using the implicit function theorem. The expressions for the derivatives require the second and third derivatives of the link w.r.t. the mean (and the 4th derivatives if Fisher scoring is not used). Also required are the first and second derivatives of the variance function w.r.t. the mean (plus the third derivative if Fisher scoring is not used). Finally REML or ML estimation of smoothing parameters requires the log saturated likelihood and its first two derivatives w.r.t. the scale parameter. These functions add functions evaluating these quantities to a family.

If the family already has functions `dvar`, `d2var`, `d3var`, `d2link`, `d3link`, `d4link` and for RE/ML `ls`, then these functions simply return the family unmodified: this allows non-standard links to be used with `gam` when using outer iteration (performance iteration operates with unmodified families). Note that if you only need Fisher scoring then `d4link` and `d3var` can be dummy, as they are ignored. Similarly `ls` is only needed for RE/ML.

The `dvar` function is a function of a mean vector, `mu`, and returns a vector of corresponding first derivatives of the family variance function. The `d2link` function is also a function of a vector of mean values, `mu`: it returns a vector of second derivatives of the link, evaluated at `mu`. Higher derivatives are defined similarly.

If modifying your own family, note that you can often get away with supplying only a `dvar` and `d2var`, function if your family only requires links that occur in one of the standard families.

## Value

A family object with extra component functions `dvar`, `d2var`, `d2link`, `d3link`, `d4link` and `ls`.

fixDependence

*Detect linear dependencies of one matrix on another*

---

## Description

Identifies columns of a matrix `X2` which are linearly dependent on columns of a matrix `X1`. Primarily of use in setting up identifiability constraints for nested GAMs.

## Usage

```
fixDependence(X1, X2, tol=.Machine$double.eps^.5)
```

**Arguments**

X1	A matrix.
X2	A matrix, the columns of which may be partially linearly dependent on the columns of X1.
tol	The tolerance to use when assessing linear dependence.

**Details**

The algorithm uses a simple approach based on QR decomposition: see Wood (2006, section 4.10.2) for details.

**Value**

An array of the columns of X2 which are linearly dependent on columns of X1. NULL if the two matrices are independent.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**References**

Wood S.N. (2006) Generalized Additive Models: An Introduction with R. Chapman and Hall/CRC Press.

**Examples**

```
n<-20;c1<-4;c2<-7
X1<-matrix(runif(n*c1),n,c1)
X2<-matrix(runif(n*c2),n,c2)
X2[,3]<-X1[,2]+X2[,4]*.1
X2[,5]<-X1[,1]*.2+X1[,2]*.04
fixDependence(X1,X2)
```

---

**Description**

Description of [gam](#) formula (see Details), and how to extract it from a fitted gam object.

**Usage**

```
## S3 method for class 'gam':
formula(x, ...)
```

**Arguments**

x	fitted model objects of class gam (see <a href="#">gamObject</a> ) as produced by gam().
...	un-used in this case

## Details

The formula supplied to `gam` is exactly like that supplied to `glm` except that smooth terms, `s` and `te` can be added to the right hand side (and `.` is not supported in `gam` formulae).

Smooth terms are specified by expressions of the form:

```
s(x1, x2, . . . , k=12, fx=FALSE, bs="tp", by=z, id=1)
```

where `x1`, `x2`, etc. are the covariates which the smooth is a function of, and `k` is the dimension of the basis used to represent the smooth term. If `k` is not specified then basis specific defaults are used. `fx` is used to indicate whether or not this term should be unpenalized, and therefore have a fixed number of degrees of freedom set by `k` (almost always `k-1`). `bs` indicates the basis to use for the smooth: the built in options are described in `smooth.terms`, and user defined smooths can be added (see `user.defined.smooth`). If `bs` is not supplied then the default "tp" (`tprs`) basis is used. `by` can be used to specify a variable by which the smooth should be multiplied. For example `gam(y~s(x, by=z))` would specify a model  $E(y) = f(x)z$  where  $f(\cdot)$  is a smooth function. The `by` option is particularly useful for models in which different functions of the same variable are required for each level of a factor and for ‘varying coefficient models’: see `gam.models`. `id` is used to give smooths identities: smooths with the same identity have the same basis, penalty and smoothing parameter (but different coefficients, so they are different functions).

An alternative for specifying smooths of more than one covariate is e.g.:

```
te(x, z, bs=c("tp", "tp"), m=c(2, 3), k=c(5, 10))
```

which would specify a tensor product smooth of the two covariates `x` and `z` constructed from marginal t.p.r.s. bases of dimension 5 and 10 with marginal penalties of order 2 and 3. Any combination of basis types is possible, as is any number of covariates. `te` provides further information.

Both `s` and `te` terms accept an `sp` argument of supplied smoothing parameters: positive values are taken as fixed values to be used, negative to indicate that the parameter should be estimated. If `sp` is supplied then it over-rides whatever is in the `sp` argument to `gam`, if it is not supplied then it defaults to all negative, but does not over-ride the `sp` argument to `gam`.

Formulae can involve nested or “overlapping” terms such as

```
y~s(x) + s(z) + s(x, z) or y~s(x, z) + s(z, v):
```

see `gam.side` for further details and examples.

Smooth terms in a `gam` formula will accept matrix arguments as covariates (and corresponding `by` variable), in which case a ‘summation convention’ is invoked. Consider the example of `s(X, Z, by=L)` where `X`, `Z` and `L` are `n` by `m` matrices. Let `F` be the `n` by `m` matrix that results from evaluating the smooth at the values in `X` and `Z`. Then the contribution to the linear predictor from the term will be `rowSums(F*L)` (note the element-wise multiplication). This convention allows the linear predictor of the GAM to depend on (a discrete approximation to) any linear functional of a smooth: see `linear.functional.terms` for more information and examples (including functional linear models/signal regression).

Note that `gam` allows any term in the model formula to be penalized (possibly by multiple penalties), via the `paraPen` argument. See `gam.models` for details and example code.

## Value

Returns the model formula, `x$formula`. Provided so that `anova` methods print an appropriate description of the model.

---

`formXtViX`*Form component of GAMM covariance matrix*

---

**Description**

This is a service routine for [gamm](#). Given,  $V$ , an estimated covariance matrix obtained using [extract.lme.cov2](#) this routine forms  $X^T V^{-1} X$  as efficiently as possible, given the structure of  $V$  (usually sparse).

**Usage**`formXtViX(V, X)`**Arguments**

<code>V</code>	A data covariance matrix list returned from <a href="#">extract.lme.cov2</a>
<code>X</code>	A model matrix.

**Details**

The covariance matrix returned by [extract.lme.cov2](#) may be in a packed and re-ordered format, since it is usually sparse. Hence a special service routine is required to form the required products involving this matrix.

**Value**

A matrix.

full.score	<i>GCV/UBRE score for use within nlm</i>
------------	--

---

### Description

Evaluates GCV/UBRE score for a GAM, given smoothing parameters. The routine calls `gam.fit` to fit the model, and is usually called by `nlm` to optimize the smoothing parameters.

This is basically a service routine for `gam`, and is not usually called directly by users. It is only used in this context for GAMs fitted by outer iteration (see `gam.outer`) when the the outer method is "nlm.fd" (see `gam` argument `optimizer`).

### Usage

```
full.score(sp, G, family, control, gamma, ...)
```

### Arguments

<code>sp</code>	The logs of the smoothing parameters
<code>G</code>	a list returned by <code>mgcv::gam.setup</code>
<code>family</code>	The family object for the GAM.
<code>control</code>	a list returned by <code>gam.control</code>
<code>gamma</code>	the degrees of freedom inflation factor (usually 1).
<code>...</code>	other arguments, typically for passing on to <code>gam.fit</code> .

### Value

The value of the GCV/UBRE score, with attribute "full.gam.object" which is the full object returned by `gam.fit`.

### Author(s)

Simon N. Wood <simon.wood@r-project.org>

---

gam	<i>Generalized additive models with integrated smoothness estimation</i>
-----	--

---

### Description

Fits a generalized additive model (GAM) to data, the term 'GAM' being taken to include any quadratically penalized GLM. The degree of smoothness of model terms is estimated as part of fitting. `gam` can also fit any GLM subject to multiple quadratic penalties (including estimation of degree of penalization). Isotropic or scale invariant smooths of any number of variables are available as model terms, as are linear functionals of such smooths; confidence/credible intervals are readily available for any quantity predicted using a fitted model; `gam` is extendable: users can add smooths.

Smooth terms are represented using penalized regression splines (or similar smoothers) with smoothing parameters selected by GCV/UBRE/AIC/REML or by regression splines with fixed degrees of freedom (mixtures of the two are permitted). Multi-dimensional smooths are

available using penalized thin plate regression splines (isotropic) or tensor product splines (when an isotropic smooth is inappropriate). For an overview of the smooths available see [smooth.terms](#). For more on specifying models see [gam.models](#), [random.effects](#) and [linear.functional.terms](#). For more on model selection see [gam.selection](#).

`gam()` is not a clone of what S-PLUS provides: the major differences are (i) that by default estimation of the degree of smoothness of model terms is part of model fitting, (ii) a Bayesian approach to variance estimation is employed that makes for easier confidence interval calculation (with good coverage probabilities), (iii) that the model can depend on any (bounded) linear functional of smooth terms, and, (iv) the parametric part of the model can be penalized, (v) simple random effects can be incorporated, and (vi) the facilities for incorporating smooths of more than one variable are different: specifically there are no `lo` smooths, but instead (a) `s` terms can have more than one argument, implying an isotropic smooth and (b) `te` smooths are provided as an effective means for modelling smooth interactions of any number of variables via scale invariant tensor product smooths. If you want a clone of what S-PLUS provides use [gam](#) from package `gam`.

For very large datasets see [bam](#), for mixed GAM see [gamm](#) and [random.effects](#).

## Usage

```
gam(formula, family=gaussian(), data=list(), weights=NULL, subset=NULL,
    na.action, offset=NULL, method="GCV.Cp",
    optimizer=c("outer", "newton"), control=gam.control(), scale=0,
    select=FALSE, knots=NULL, sp=NULL, min.sp=NULL, H=NULL, gamma=1,
    fit=TRUE, paraPen=NULL, G=NULL, in.out, ...)
```

## Arguments

<code>formula</code>	A GAM formula (see <a href="#">formula.gam</a> and also <a href="#">gam.models</a> ). This is exactly like the formula for a GLM except that smooth terms, <code>s</code> and <code>te</code> can be added to the right hand side to specify that the linear predictor depends on smooth functions of predictors (or linear functionals of these).
<code>family</code>	This is a family object specifying the distribution and link to use in fitting etc. See <a href="#">glm</a> and <a href="#">family</a> for more details. A negative binomial family is provided: see <a href="#">negbin</a> .
<code>data</code>	A data frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from <code>environment(formula)</code> : typically the environment from which <code>gam</code> is called.
<code>weights</code>	prior weights on the data.
<code>subset</code>	an optional vector specifying a subset of observations to be used in the fitting process.
<code>na.action</code>	a function which indicates what should happen when the data contain 'NA's. The default is set by the 'na.action' setting of 'options', and is 'na.fail' if that is unset. The "factory-fresh" default is 'na.omit'.
<code>offset</code>	Can be used to supply a model offset for use in fitting. Note that this offset will always be completely ignored when predicting, unlike an offset included in <code>formula</code> : this conforms to the behaviour of <code>lm</code> and <code>glm</code> .
<code>control</code>	A list of fit control parameters returned by <a href="#">gam.control</a> .
<code>method</code>	The smoothing parameter estimation method. "GCV.Cp" to use GCV for unknown scale parameter and Mallows' Cp/UBRE/AIC for known scale. "GACV.Cp" is equivalent, but using GACV in place of GCV. "REML" for

	REML estimation, including of unknown scale, "P-REML" for REML estimation, but using a Pearson estimate of the scale. "ML" and "P-ML" are similar, but using maximum likelihood in place of REML.
optimizer	An array specifying the numerical optimization method to use to optimize the smoothing parameter estimation criterion (given by method). "perf" for performance iteration. "outer" for the more stable direct approach. "outer" can use several alternative optimizers, specified in the second element of optimizer: "newton" (default), "bfgs", "optim", "nlm" and "nlm.fd" (the latter is based entirely on finite differenced derivatives and is very slow).
scale	If this is positive then it is taken as the known scale parameter. Negative signals that the scale parameter is unknown. 0 signals that the scale parameter is 1 for Poisson and binomial and unknown otherwise. Note that (RE)ML methods can only work with scale parameter 1 for the Poisson and binomial cases.
select	If this is TRUE then gam can add an extra penalty to each term so that it can be penalized to zero. This means that the smoothing parameter estimation that is part of fitting can completely remove terms from the model. If the corresponding smoothing parameter is estimated as zero then the extra penalty has no effect.
knots	this is an optional list containing user specified knot values to be used for basis construction. For most bases the user simply supplies the knots to be used, which must match up with the k value supplied (note that the number of knots is not always just k). See <code>tprs</code> for what happens in the "tp"/"ts" case. Different terms can use different numbers of knots, unless they share a covariate.
sp	A vector of smoothing parameters can be provided here. Smoothing parameters must be supplied in the order that the smooth terms appear in the model formula. Negative elements indicate that the parameter should be estimated, and hence a mixture of fixed and estimated parameters is possible. If smooths share smoothing parameters then <code>length(sp)</code> must correspond to the number of underlying smoothing parameters.
min.sp	Lower bounds can be supplied for the smoothing parameters. Note that if this option is used then the smoothing parameters <code>full.sp</code> , in the returned object, will need to be added to what is supplied here to get the smoothing parameters actually multiplying the penalties. <code>length(min.sp)</code> should always be the same as the total number of penalties (so it may be longer than <code>sp</code> , if smooths share smoothing parameters).
H	A user supplied fixed quadratic penalty on the parameters of the GAM can be supplied, with this as its coefficient matrix. A common use of this term is to add a ridge penalty to the parameters of the GAM in circumstances in which the model is close to un-identifiable on the scale of the linear predictor, but perfectly well defined on the response scale.
gamma	It is sometimes useful to inflate the model degrees of freedom in the GCV or UBRE/AIC score by a constant multiplier. This allows such a multiplier to be supplied.
fit	If this argument is TRUE then gam sets up the model and fits it, but if it is FALSE then the model is set up and an object G containing what would be required to fit is returned. See argument G.
paraPen	optional list specifying any penalties to be applied to parametric model terms. <a href="#">gam.models</a> explains more.

G	Usually NULL, but may contain the object returned by a previous call to <code>gam</code> with <code>fit=FALSE</code> , in which case all other arguments are ignored except for <code>gamma</code> , <code>in.out</code> , <code>scale</code> , <code>control</code> , <code>method</code> optimizer and <code>fit</code> .
<code>in.out</code>	optional list for initializing outer iteration. If supplied then this must contain two elements: <code>sp</code> should be an array of initialization values for all smoothing parameters (there must be a value for all smoothing parameters, whether fixed or to be estimated, but those for fixed s.p.s are not used); <code>scale</code> is the typical scale of the GCV/UBRE function, for passing to the outer optimizer.
...	further arguments for passing on e.g. to <code>gam.fit</code> (such as <code>mustart</code> ).

## Details

A generalized additive model (GAM) is a generalized linear model (GLM) in which the linear predictor is given by a user specified sum of smooth functions of the covariates plus a conventional parametric component of the linear predictor. A simple example is:

$$\log(E(y_i)) = f_1(x_{1i}) + f_2(x_{2i})$$

where the (independent) response variables  $y_i \sim \text{Poi}$ , and  $f_1$  and  $f_2$  are smooth functions of covariates  $x_1$  and  $x_2$ . The log is an example of a link function.

If absolutely any smooth functions were allowed in model fitting then maximum likelihood estimation of such models would invariably result in complex overfitting estimates of  $f_1$  and  $f_2$ . For this reason the models are usually fit by penalized likelihood maximization, in which the model (negative log) likelihood is modified by the addition of a penalty for each smooth function, penalizing its ‘wiggleness’. To control the tradeoff between penalizing wiggleness and penalizing badness of fit each penalty is multiplied by an associated smoothing parameter: how to estimate these parameters, and how to practically represent the smooth functions are the main statistical questions introduced by moving from GLMs to GAMs.

The `mgcv` implementation of `gam` represents the smooth functions using penalized regression splines, and by default uses basis functions for these splines that are designed to be optimal, given the number basis functions used. The smooth terms can be functions of any number of covariates and the user has some control over how smoothness of the functions is measured.

`gam` in `mgcv` solves the smoothing parameter estimation problem by using the Generalized Cross Validation (GCV) criterion

$$nD/(n - DoF)^2$$

or an Un-Biased Risk Estimator (UBRE) criterion

$$D/n + 2sDoF/n - s$$

where  $D$  is the deviance,  $n$  the number of data,  $s$  the scale parameter and  $DoF$  the effective degrees of freedom of the model. Notice that UBRE is effectively just AIC rescaled, but is only used when  $s$  is known.

Alternatives are GACV, or a Laplace approximation to REML. There is some evidence that the latter may actually be the most effective choice.

Smoothing parameters are chosen to minimize the GCV, UBRE/AIC, GACV or REML scores for the model, and the main computational challenge solved by the `mgcv` package is to do this efficiently and reliably. Various alternative numerical methods are provided which can be set by argument `optimizer`.

Broadly `gam` works by first constructing basis functions and one or more quadratic penalty coefficient matrices for each smooth term in the model formula, obtaining a model matrix for the strictly parametric part of the model formula, and combining these to obtain a complete model

matrix (/design matrix) and a set of penalty matrices for the smooth terms. Some linear identifiability constraints are also obtained at this point. The model is fit using `gam.fit`, a modification of `glm.fit`. The GAM penalized likelihood maximization problem is solved by Penalized Iteratively Reweighted Least Squares (P-IRLS) (see e.g. Wood 2000). Smoothing parameter selection is integrated in one of two ways. (i) ‘Performance iteration’ uses the fact that at each P-IRLS iteration a penalized weighted least squares problem is solved, and the smoothing parameters of that problem can be estimated by GCV or UBRE. Eventually, in most cases, both model parameter estimates and smoothing parameter estimates converge. (ii) Alternatively the P-IRLS scheme is iterated to convergence for each trial set of smoothing parameters, and GCV, UBRE or REML scores are only evaluated on convergence - optimization is then ‘outer’ to the P-IRLS loop: in this case the P-IRLS iteration has to be differentiated, to facilitate optimization, and `gam.fit3` is used in place of `gam.fit`. The default is the second method, outer iteration.

Several alternative basis-penalty types are built in for representing model smooths, but alternatives can easily be added (see `smooth.terms` for an overview and `smooth.construct` for how to add smooth classes). In practice the default basis is usually the best choice, but the choice of the basis dimension ( $k$  in the `s` and `te` terms) is something that should be considered carefully (the exact value is not critical, but it is important not to make it restrictively small, nor very large and computationally costly). The basis should be chosen to be larger than is believed to be necessary to approximate the smooth function concerned. The effective degrees of freedom for the smooth will then be controlled by the smoothing penalty on the term, and (usually) selected automatically (with an upper limit set by  $k-1$  or occasionally  $k$ ). Of course the  $k$  should not be made too large, or computation will be slow (or in extreme cases there will be more coefficients to estimate than there are data).

Note that `gam` assumes a very inclusive definition of what counts as a GAM: basically any penalized GLM can be used: to this end `gam` allows the non smooth model components to be penalized via argument `paraPen` and allows the linear predictor to depend on general linear functionals of smooths, via the summation convention mechanism described in `linear.functional.terms`.

Details of the default underlying fitting methods are given in Wood (2004 and 2008). Some alternative methods are discussed in Wood (2000 and 2006).

### Value

If `fit=FALSE` the function returns a list `G` of items needed to fit a GAM, but doesn’t actually fit it. Otherwise the function returns an object of class "gam" as described in `gamObject`.

### WARNINGS

You must have more unique combinations of covariates than the model has total parameters. (Total parameters is sum of basis dimensions plus sum of non-spline terms less the number of spline terms).

Automatic smoothing parameter selection is not likely to work well when fitting models to very few response data.

For data with many zeroes clustered together in the covariate space it is quite easy to set up GAMs which suffer from identifiability problems, particularly when using Poisson or binomial families. The problem is that with e.g. log or logit links, mean value zero corresponds to an infinite range on the linear predictor scale.

### Author(s)

Simon N. Wood <simon.wood@r-project.org>

Front end design inspired by the S function of the same name based on the work of Hastie and Tibshirani (1990). Underlying methods owe much to the work of Wahba (e.g. 1990) and Gu (e.g. 2002).

gam.check

*Some diagnostics for a fitted gam model*

---

## Description

Takes a fitted `gam` object produced by `gam()` and produces some diagnostic information about the fitting procedure and results. The default is to produce 4 residual plots, and some information about the convergence of the smoothness selection optimization.

## Usage

```
gam.check(b, ...)
```

## Arguments

`b` a fitted `gam` object as produced by `gam()`.

`...` extra graphics parameters to pass to plotting functions.

## Details

This function plots 4 standard diagnostic plots, and some other convergence diagnostics. Usually the 4 plots are various residual plots. The printed information relates to the optimization used to select smoothing parameters. For the default optimization methods the information is summarized in a readable way, but for other optimization methods, whatever is returned by way of convergence diagnostics is simply printed.

---

gam.control

*Setting GAM fitting defaults*

---

## Description

This is an internal function of package `mgcv` which allows control of the numerical options for fitting a GAM. Typically users will want to modify the defaults if model fitting fails to converge, or if the warnings are generated which suggest a loss of numerical stability during fitting. To change the default choice of fitting method, see `gam` arguments `method` and `optimizer`.

## Usage

```
gam.control(irls.reg=0.0, epsilon = 1e-06, maxit = 100,
            mgcv.tol=1e-7, mgcv.half=15, trace = FALSE,
            rank.tol=.Machine$double.eps^0.5,
            nlm=list(), optim=list(), newton=list(),
            outerPIsteps=0, idLinksBases=TRUE, scalePenalty=TRUE,
            keepData=FALSE)
```

**Arguments**

<code>irls.reg</code>	For most models this should be 0. The iteratively re-weighted least squares method by which GAMs are fitted can fail to converge in some circumstances. For example, data with many zeroes can cause problems in a model with a log link, because a mean of zero corresponds to an infinite range of linear predictor values. Such convergence problems are caused by a fundamental lack of identifiability, but do not show up as lack of identifiability in the penalized linear model problems that have to be solved at each stage of iteration. In such circumstances it is possible to apply a ridge regression penalty to the model to impose identifiability, and <code>irls.reg</code> is the size of the penalty.
<code>epsilon</code>	This is used for judging conversion of the GLM IRLS loop in <code>gam.fit</code> or <code>gam.fit3</code> .
<code>maxit</code>	Maximum number of IRLS iterations to perform.
<code>mgcv.tol</code>	The convergence tolerance parameter to use in GCV/UBRE optimization.
<code>mgcv.half</code>	If a step of the GCV/UBRE optimization method leads to a worse GCV/UBRE score, then the step length is halved. This is the number of halvings to try before giving up.
<code>trace</code>	Set this to TRUE to turn on diagnostic output.
<code>rank.tol</code>	The tolerance used to estimate the rank of the fitting problem, for methods which deal with rank deficient cases (basically all except those based on <code>mgcv</code> ).
<code>nlm</code>	list of control parameters to pass to <code>nlm</code> if this is used for outer estimation of smoothing parameters (not default). See details.
<code>optim</code>	list of control parameters to pass to <code>optim</code> if this is used for outer estimation of smoothing parameters (not default). See details.
<code>newton</code>	list of control parameters to pass to default Newton optimizer used for outer estimation of log smoothing parameters. See details.
<code>outerPIsteps</code>	The number of performance iteration steps used to initialize outer iteration.
<code>idLinksBases</code>	If smooth terms have their smoothing parameters linked via the <code>id</code> mechanism (see <code>s</code> ), should they also have the same bases. Set this to FALSE only if you are sure you know what you are doing (you should almost surely set <code>scalePenalty</code> to FALSE as well in this case).
<code>scalePenalty</code>	<code>gamm</code> is somewhat sensitive to the absolute scaling of the penalty matrices of a smooth relative to its model matrix. This option rescales the penalty matrices to accomodate this problem. Probably should be set to FALSE if you are linking smoothing parameters but have set <code>idLinkBases</code> to FALSE.
<code>keepData</code>	Should a copy of the original <code>data</code> argument be kept in the <code>gam</code> object? Strict compatibility with class <code>glm</code> would keep it, but it wastes space to do so.

**Details**

Outer iteration using `newton` is controlled by the list `newton` with the following elements: `conv.tol` (default 1e-6) is the relative convergence tolerance; `maxNstep` is the maximum length allowed for an element of the Newton search direction (default 5); `maxSstep` is the maximum length allowed for an element of the steepest descent direction (only used if Newton fails - default 2); `maxHalf` is the maximum number of step halvings to permit before giving up (default 30).

If outer iteration using `nlm` is used for fitting, then the control list `nlm` stores control arguments for calls to routine `nlm`. The list has the following named elements: (i) `ndigit` is the number of significant digits in the GCV/UBRE score - by default this is worked out from `epsilon`; (ii)

`gradtol` is the tolerance used to judge convergence of the gradient of the GCV/UBRE score to zero - by default set to  $10 \times \text{epsilon}$ ; (iii) `stepmax` is the maximum allowable log smoothing parameter step - defaults to 2; (iv) `steptol` is the minimum allowable step length - defaults to  $1e-4$ ; (v) `iterlim` is the maximum number of optimization steps allowed - defaults to 200; (vi) `check.analyticals` indicates whether the built in exact derivative calculations should be checked numerically - defaults to FALSE. Any of these which are not supplied and named in the list are set to their default values.

Outer iteration using `optim` is controlled using list `optim`, which currently has one element: `factr` which takes default value  $1e7$ .

gam.convergence

*GAM convergence and performance issues*

---

### Description

When fitting GAMs there is a tradeoff between speed of fitting and probability of fit convergence. The default fitting options, specified by `gam` arguments `method` and `optimizer`, opt for certainty of convergence over speed of fit. In the Generalized Additive Model case it means using ‘outer’ iteration in preference to ‘performance iteration’: see [gam.outer](#) for details.

It is possible for the default ‘outer’ iteration to fail when finding initial smoothing parameters using a few steps of performance iteration (if you get a convergence failure message from `magic` when outer iterating, then this is what has happened): lower `outerPIsteps` in [gam.control](#) to fix this.

There are three things that you can try to speed up GAM fitting. (i) if you have large numbers of smoothing parameters in the generalized case, then try the `"bfgs"` method option in `gam` argument `optimizer`: this can be faster than the default. (ii) Change the `optimizer` argument to `gam` so that ‘performance iteration’ is used in place of the default outer iteration. Usually performance iteration converges well and it can sometimes be quicker than the default outer iteration. (iii) For large datasets it may be worth changing the smoothing basis to use `bs="cr"` (see [s](#) for details) for 1-d smooths, and to use `te` smooths in place of `s` smooths for smooths of more than one variable. This is because the default thin plate regression spline basis `"tp"` is costly to set up for large datasets (much over 1000 data, say).

If the GAM estimation process fails to converge when using performance iteration, then switch to outer iteration via the `optimizer` argument of `gam`. If it still fails, try increasing the number of IRLS iterations (see `gam.control`) or perhaps experiment with the convergence tolerance.

If you still have problems, it's worth noting that a GAM is just a (penalized) GLM and the IRLS scheme used to estimate GLMs is not guaranteed to converge. Hence non convergence of a GAM may relate to a lack of stability in the basic IRLS scheme. Therefore it is worth trying to establish whether the IRLS iterations are capable of converging. To do this fit the problematic GAM with all smooth terms specified with `fx=TRUE` so that the smoothing parameters are all fixed at zero. If this 'largest' model can converge then, then the maintainer would quite like to know about your problem! If it doesn't converge, then its likely that your model is just too flexible for the IRLS process itself. Having tried increasing `maxit` in `gam.control`, there are several other possibilities for stabilizing the iteration. It is possible to try (i) setting lower bounds on the smoothing parameters using the `min.sp` argument of `gam`: this may or may not change the model being fitted; (ii) reducing the flexibility of the model by reducing the basis dimensions `k` in the specification of `s` and `te` model terms: this obviously changes the model being fitted somewhat; (iii) introduce a small regularization term into the fitting via the `irls.reg` argument of `gam.control`: this option obviously changes the nature of the fit somewhat, since parameter estimates are pulled towards zero by doing this.

Usually, a major contributor to fitting difficulties is that the model is a very poor description of the data.

gam.fit

*GAM P-IRLS estimation with GCV/UBRE smoothness estimation*

---

#### Description

This is an internal function of package `mgcv`. It is a modification of the function `glm.fit`, designed to be called from `gam`. The major modification is that rather than solving a weighted least squares problem at each IRLS step, a weighted, penalized least squares problem is solved at each IRLS step with smoothing parameters associated with each penalty chosen by GCV or UBRE, using routine `magic`. For further information on usage see code for `gam`. Some regularization of the IRLS weights is also permitted as a way of addressing identifiability related problems (see `gam.control`). Negative binomial parameter estimation is supported.

The basic idea of estimating smoothing parameters at each step of the P-IRLS is due to Gu (1992), and is termed 'performance iteration' or 'performance oriented iteration'.

#### Usage

```
gam.fit(G, start = NULL, etastart = NULL,
        mustart = NULL, family = gaussian(),
        control = gam.control(), gamma=1,
        fixedSteps=(control$maxit+1), ...)
```

**Arguments**

G	An object of the type returned by <code>gam</code> when <code>fit=FALSE</code> .
start	Initial values for the model coefficients.
etastart	Initial values for the linear predictor.
mustart	Initial values for the expected response.
family	The family object, specifying the distribution and link to use.
control	Control option list as returned by <code>gam.control</code> .
gamma	Parameter which can be increased to up the cost of each effective degree of freedom in the GCV or AIC/UBRE objective.
fixedSteps	How many steps to take: useful when only using this routine to get rough starting values for other methods.
...	Other arguments: ignored.

**Value**

A list of fit information.

gam.fit3

*P-IRLS GAM estimation with GCV & UBRE/AIC or RE/ML derivative calculation*

---

**Description**

Estimation of GAM smoothing parameters is most stable if optimization of the UBRE/AIC, GCV, GACV, REML or ML score is outer to the penalized iteratively re-weighted least squares scheme used to estimate the model given smoothing parameters.

This routine estimates a GAM (any quadratically penalized GLM) given log smoothing parameters, and evaluates derivatives of the smoothness selection scores of the model with respect to the log smoothing parameters. Calculation of exact derivatives is generally faster than approximating them

by finite differencing, as well as generally improving the reliability of GCV/UBRE/AIC/REML score minimization.

The approach is to run the P-IRLS to convergence, and only then to iterate for first and second derivatives.

Not normally called directly, but rather service routines for `gam`.

### Usage

```
gam.fit3(x, y, sp, Eb, UrS=list(),
        weights = rep(1, nobs), start = NULL, etastart = NULL,
        mustart = NULL, offset = rep(0, nobs), U1 = diag(ncol(x)),
        Mp = -1, family = gaussian(), control = gam.control(),
        intercept = TRUE, deriv=2, gamma=1, scale=1,
        printWarn=TRUE, scoreType="REML", null.coef=rep(0, ncol(x)),
        pearson.extra=0, dev.extra=0, n.true=-1, ...)
```

### Arguments

<code>x</code>	The model matrix for the GAM (or any penalized GLM).
<code>y</code>	The response variable.
<code>sp</code>	The log smoothing parameters.
<code>Eb</code>	A balanced version of the total penalty matrix: used for numerical rank determination.
<code>UrS</code>	List of square root penalties premultiplied by transpose of orthogonal basis for the total penalty.
<code>weights</code>	prior weights for fitting.
<code>start</code>	optional starting parameter guesses.
<code>etastart</code>	optional starting values for the linear predictor.
<code>mustart</code>	optional starting values for the mean.
<code>offset</code>	the model offset
<code>U1</code>	An orthogonal basis for the range space of the penalty — required for ML smoothness estimation only.
<code>Mp</code>	The dimension of the total penalty null space — required for ML smoothness estimation only.
<code>family</code>	the family - actually this routine would never be called with <code>gaussian()</code>
<code>control</code>	control list as returned from <code>glm.control</code>
<code>intercept</code>	does the model have an intercept, TRUE or FALSE
<code>deriv</code>	Should derivatives of the GCV and UBRE/AIC scores be calculated? 0, 1 or 2, indicating the maximum order of differentiation to apply.
<code>gamma</code>	The weight given to each degree of freedom in the GCV and UBRE scores can be varied (usually increased) using this parameter.
<code>scale</code>	The scale parameter - needed for the UBRE/AIC score.
<code>printWarn</code>	Set to FALSE to suppress some warnings. Useful in order to ensure that some warnings are only printed if they apply to the final fitted model, rather than an intermediate used in optimization.
<code>scoreType</code>	specifies smoothing parameter selection criterion to use.

<code>null.coef</code>	coefficients for a model which gives some sort of upper bound on deviance. This allows immediate divergence problems to be controlled.
<code>pearson.extra</code>	Extra component to add to numerator of pearson statistic in P-REML/P-ML smoothness selection criteria.
<code>dev.extra</code>	Extra component to add to deviance for REML/ML type smoothness selection criteria.
<code>n.true</code>	Number of data to assume in smoothness selection criteria. $\leq 0$ indicates that it should be the number of rows of X.
<code>...</code>	Other arguments: ignored.

### Details

This routine is basically `glm.fit` with some modifications to allow (i) for quadratic penalties on the log likelihood; (ii) derivatives of the model coefficients with respect to log smoothing parameters to be obtained by use of the implicit function theorem and (iii) derivatives of the GAM GCV, UBRE/AIC, REML or ML scores to be evaluated at convergence.

In addition the routines apply step halving to any step that increases the penalized deviance substantially.

The most costly parts of the calculations are performed by calls to compiled C code (which in turn calls LAPACK routines) in place of the compiled code that would usually perform least squares estimation on the working model in the IRLS iteration.

Estimation of smoothing parameters by optimizing GCV scores obtained at convergence of the P-IRLS iteration was proposed by O'Sullivan et al. (1986), and is here termed 'outer' iteration.

Note that use of non-standard families with this routine requires modification of the families as described in [fix.family.link](#).

### Author(s)

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

The routine has been modified from `glm.fit` in R 2.0.1, written by the R core (see `glm.fit` for further credits).

## Description

This page is intended to provide some more information on how to specify GAMs. A GAM is a GLM in which the linear predictor depends, in part, on a sum of smooth functions of predictors and (possibly) linear functionals of smooth functions of (possibly dummy) predictors.

Specifically let  $y_i$  denote an independent random variable with mean  $\mu_i$  and an exponential family distribution, or failing that a known mean variance relationship suitable for use of quasi-likelihood methods. Then the the linear predictor of a GAM has a structure something like

$$g(\mu_i) = \mathbf{X}_i\beta + f_1(x_{1i}, x_{2i}) + f_2(x_{3i}) + L_i f_3(x_4) + \dots$$

where  $g$  is a known smooth monotonic ‘link’ function,  $\mathbf{X}_i\beta$  is the parametric part of the linear predictor, the  $x_j$  are predictor variables, the  $f_j$  are smooth functions and  $L_i$  is some linear functional of  $f_3$ . There may of course be multiple linear functional terms, or none.

The key idea here is that the dependence of the response on the predictors can be represented as a parametric sub-model plus the sum of some (functionals of) smooth functions of one or more of the predictor variables. Thus the model is quite flexible relative to strictly parametric linear or generalized linear models, but still has much more structure than the completely general model that says that the response is just some smooth function of all the covariates.

Note one important point. In order for the model to be identifiable the smooth functions usually have to be constrained to have zero mean (usually taken over the set of covariate values). The constraint is needed if the term involving the smooth includes a constant function in its span. `gam` always applies such constraints unless there is a `by` variable present, in which case an assessment is made of whether the constraint is needed or not (see below).

The following sections discuss specifying model structures for `gam`. Specification of the distribution and link function is done using the `family` argument to `gam` and works in the same way as for `glm`. This page therefore concentrates on the model formula for `gam`.

## Models with simple smooth terms

Consider the example model.

$$g(\mu_i) = \beta_0 + \beta_1 x_{1i} + \beta_2 x_{2i} + f_1(x_{3i}) + f_2(x_{4i}, x_{5i})$$

where the response variables  $y_i$  has expectation  $\mu_i$  and  $g$  is a link function.

The `gam` formula for this would be

```
y ~ x1 + x2 + s(x3) + s(x4, x5).
```

This would use the default basis for the smooths (a thin plate regression spline basis for each), with automatic selection of the effective degrees of freedom for both smooths. The dimension of the smoothing basis is given a default value as well (the dimension of the basis sets an upper limit on the maximum possible degrees of freedom for the basis - the limit is typically one less than basis dimension). Full details of how to control smooths are given in `s` and `te`, and further discussion of basis dimension choice can be found in `choose.k`. For the moment suppose that we would like to change the basis of the first smooth to a cubic regression spline basis with a dimension of 20, while fixing the second term at 25 degrees of freedom. The appropriate formula would be:

```
y ~ x1 + x2 + s(x3, bs="cr", k=20) + s(x4, x5, k=26, fx=TRUE).
```

The above assumes that  $x_4$  and  $x_5$  are naturally on similar scales (e.g. they might be co-ordinates), so that isotropic smoothing is appropriate. If this assumption is false then tensor product smoothing might be better (see [te](#)).

$y \sim x_1 + x_2 + s(x_3) + te(x_4, x_5)$

would generate a tensor product smooth of  $x_4$  and  $x_5$ . By default this smooth would have basis dimension 25 and use cubic regression spline marginals. Varying the defaults is easy. For example  $y \sim x_1 + x_2 + s(x_3) + te(x_4, x_5, bs=c("cr", "ps"), k=c(6, 7))$  specifies that the tensor product should use a rank 6 cubic regression spline marginal and a rank 7 P-spline marginal to create a smooth with basis dimension 42.

### Nested terms

Another common modelling task is to decide if a model like:

$$E(y_i) = f(x_i, z_i)$$

is really necessary or whether:

$$E(y_i) = f_1(x_i) + f_2(z_i)$$

would do just as well. One possibility is to examine the results of fitting:

$y \sim s(x) + s(z) + s(x, z)$ .

gam automatically generates side conditions to make this model identifiable. You can also estimate ‘overlapping’ models like:

$y \sim s(x, z) + s(z, v)$ .

Note that optimum interpretability of such models is obtained by ensuring that lower order terms are strictly nested with higher order ones. This is most easily achieved by employing tensor product smooths for multidimensional terms, and ensuring that lower order terms are using the same (marginal) bases as higher order ones. For example:

$y \sim s(x, bs="cr", k=5) + s(z, bs="cr", k=5) + te(x, z)$

would ensure strict nesting of the main effects within the interaction (given the [te](#) default `bs` and `k` arguments), since the main effects employ the same bases used as marginals for the [te](#) term.

### ‘by’ variables

by variables are the means for constructing ‘varying-coefficient models’ (geographic regression models) and for letting smooths ‘interact’ with factors or parametric terms. They are also the key to specifying general linear functionals of smooths.

The `s` and `te` terms used to specify smooths accept an argument `by`, which is a numeric or factor variable of the same dimension as the covariates of the smooth. If a `by` variable is numeric, then its  $i^{th}$  element multiplies the  $i^{th}$  row of the model matrix corresponding to the smooth term concerned. If a `by` variable is a factor then it generates an indicator vector for each level of the factor. The model matrix for the smooth term is then replicated for each factor level, and each copy has its rows multiplied by the corresponding rows of its indicator variable. The smoothness penalties are also duplicated for each factor level. In short a different smooth is generated for each factor level (the `id` argument to `s` and `te` can be used to force all such smooths to have the same smoothing parameter).

As an example, consider the model

$$E(y_i) = \beta_0 + f(x_i)z_i$$

where  $f$  is a smooth function, and  $z_i$  is a numeric variable. The appropriate formula is:

$y \sim s(x, by=z)$

- the `by` argument ensures that the smooth function gets multiplied by covariate  $z$ . Note that when

using factor variables, then the presence of centering constraints usually means that the by variable should be included as a parametric term, as well.

The example code below also illustrates the use of factor by variables.

by variables may be supplied as numeric matrices as part of specifying general linear functional terms.

If a by variable is present and numeric (rather than a factor) then the corresponding smooth is only subjected to an identifiability constraint if (i) the by variable is a constant vector, or, (ii) for a matrix by variable,  $L$ , if  $L \%*\% \text{rep}(1, \text{ncol}(L))$  is constant or (iii) if a user defined smooth constructor supplies an identifiability constraint explicitly.

### Linking smooths with ‘id’

It is sometimes desirable to insist that different smooth terms have the same degree of smoothness. This can be done by using the `id` argument to `s` or `te` terms. Smooths which share an `id` will have the same smoothing parameter. Really this only makes sense if the smooths use the same basis functions, and the default behaviour is to force this to happen: all smooths sharing an `id` have the same basis functions as the first smooth occurring with that `id`. Note that if you want exactly the same function for each smooth, then this is best achieved by making use of the summation convention covered under ‘linear functional terms’.

As an example suppose that  $E(y_i) \equiv \mu_i$  and

$$g(\mu_i) = f_1(x_{1i}) + f_2(x_{2i}, x_{3i}) + f_3(x_{4i})$$

but that  $f_1$  and  $f_3$  should have the same smoothing parameters (and  $x_2$  and  $x_3$  are on different scales). Then the `gam` formula

```
y ~ s(x1, id=1) + te(x_2, x3) + s(x4, id=1)
```

would achieve the desired result. `id` can be numbers or character strings. Giving an `id` to a term with a factor by variable causes the smooths at each level of the factor to have the same smoothing parameter.

Smooth term `ids` are not supported by `gamm`.

### Linear functional terms

General linear functional terms have a long history in the spline literature including in the penalized GLM context (see e.g. Wahba 1990). Such terms encompass varying coefficient models/ geographic regression, functional GLMs (i.e. GLMs with functional predictors), GLASS models, etc, and allow smoothing with respect to aggregated covariate values, for example.

Such terms are implemented in `mgcv` using a simple ‘summation convention’ for smooth terms: If the covariates of a smooth are supplied as matrices, then summation of the evaluated smooth over the columns of the matrices is implied. Each covariate matrix and any by variable matrix must be of the same dimension. Consider, for example the term

```
s(X, Z, by=L)
```

where  $X$ ,  $Z$  and  $L$  are  $n \times p$  matrices. Let  $f$  denote the thin plate regression spline specified. The resulting contribution to the  $i^{\text{th}}$  element of the linear predictor is

$$\sum_{j=1}^p L_{ij} f(X_{ij}, Z_{ij})$$

If no  $L$  is supplied then all its elements are taken as 1. In R code terms, let  $F$  denote the  $n \times p$  matrix obtained by evaluating the smooth at the values in  $X$  and  $Z$ . Then the contribution of the term to the linear predictor is `rowSums(L*F)` (note that it’s element by element multiplication here!).

The summation convention applies to `te` terms as well as `s` terms. More details and examples are provided in [linear.functional.terms](#).

## Random effects

Random effects can be added to gam models using `s(...,bs="re")` terms (see [smooth.construct.re.smooth.spec](#)), or the `paraPen` argument to `gam` covered below. See [gam.vcomp](#), [random.effects](#) and [smooth.construct.re.smooth.spec](#) for further details. An alternative is to use the approach of `gamm`.

## Penalizing the parametric terms

In case the ability to add smooth classes, smooth identities, by variables and the summation convention are still not sufficient to implement exactly the penalized GLM that you require, `gam` also allows you to penalize the parametric terms in the model formula. This is mostly useful in allowing one or more matrix terms to be included in the formula, along with a sequence of quadratic penalty matrices for each.

Suppose that you have set up a model matrix  $\mathbf{X}$ , and want to penalize the corresponding coefficients,  $\beta$  with two penalties  $\beta^T \mathbf{S}_1 \beta$  and  $\beta^T \mathbf{S}_2 \beta$ . Then something like the following would be appropriate: `gam(y ~ X - 1, paraPen=list(X=list(S1, S1)))`

The `paraPen` argument should be a list with elements having names corresponding to the terms being penalized. Each element of `paraPen` is itself a list, with optional elements `L`, `rank` and `sp`: all other elements must be penalty matrices. If present, `rank` is a vector giving the rank of each penalty matrix (if absent this is determined numerically). `L` is a matrix that maps underlying log smoothing parameters to the log smoothing parameters that actually multiply the individual quadratic penalties: taken as the identity if not supplied. `sp` is a vector of (underlying) smoothing parameter values: positive values are taken as fixed, negative to signal that the smoothing parameter should be estimated. Taken as all negative if not supplied.

An obvious application of `paraPen` is to incorporate random effects, and an example of this is provided below. In this case the supplied penalty matrices will be (generalized) inverse covariance matrices for the random effects — i.e. precision matrices. The final estimate of the covariance matrix corresponding to one of these penalties is given by the (generalized) inverse of the penalty matrix multiplied by the estimated scale parameter and divided by the estimated smoothing parameter for the penalty. For example, if you use an identity matrix to penalize some coefficients that are to be viewed as i.i.d. Gaussian random effects, then their estimated variance will be the estimated scale parameter divided by the estimate of the smoothing parameter, for this penalty. See the ‘rail’ example below.

gam.outer

*Minimize GCV or UBRE score of a GAM using 'outer' iteration***Description**

Estimation of GAM smoothing parameters is most stable if optimization of the smoothness selection score (GCV, GACV, UBRE/AIC, REML, ML etc) is outer to the penalized iteratively re-weighted least squares scheme used to estimate the model given smoothing parameters.

This routine optimizes a smoothness selection score in this way. Basically the score is evaluated for each trial set of smoothing parameters by estimating the GAM for those smoothing parameters. The score is minimized w.r.t. the parameters numerically, using `newton` (default), `bfgs`, `optim` or `nlm`. Exact (first and second) derivatives of the score can be used by fitting with `gam.fit3`. This improves efficiency and reliability relative to relying on finite difference derivatives.

Not normally called directly, but rather a service routine for `gam`.

**Usage**

```
gam.outer(lsp, fscale, family, control, method, optimizer,
  criterion, scale, gamma, G, ...)
```

**Arguments**

<code>lsp</code>	The log smoothing parameters.
<code>fscale</code>	Typical scale of the GCV or UBRE/AIC score.
<code>family</code>	the model family.
<code>control</code>	control argument to pass to <code>gam.fit</code> if pure finite differencing is being used.
<code>method</code>	method argument to <code>gam</code> defining the smoothness criterion to use (but depending on whether or not scale known).
<code>optimizer</code>	The argument to <code>gam</code> defining the numerical optimization method to use.
<code>criterion</code>	Which smoothness selection criterion to use. One of "UBRE", "GCV", "GACV", "REML" or "P-REML".
<code>scale</code>	Supplied scale parameter. Positive indicates known.
<code>gamma</code>	The degree of freedom inflation factor for the GCV/UBRE/AIC score.

- G List produced by `mgcv::gam.setup`, containing most of what's needed to actually fit a GAM.
- ... other arguments, typically for passing on to `gam.fit3` (ultimately).

### Details

See Wood (2008) for full details on 'outer iteration'.

gam.selection

*Generalized Additive Model Selection*

---

### Description

This page is intended to provide some more information on how to select GAMs. In particular, it gives a brief overview of smoothness selection, and then discusses how this can be extended to select inclusion/exclusion of terms. Hypothesis testing approaches to the latter problem are also discussed.

### Smoothness selection criteria

Given a model structure specified by a gam model formula, `gam()` attempts to find the appropriate smoothness for each applicable model term using prediction error criteria or likelihood based methods. The prediction error criteria used are Generalized (Approximate) Cross Validation (GCV or GACV) when the scale parameter is unknown or an Un-Biased Risk Estimator (UBRE) when it is known. UBRE is essentially scaled AIC (Generalized case) or Mallows'  $C_p$  (additive model case). GCV and UBRE are covered in Craven and Wahba (1979) and Wahba (1990). Alternatively REML of maximum likelihood (ML) may be used for smoothness selection, by viewing the smooth components as random effects (in this case the variance component for each smooth random effect will be given by the scale parameter divided by the smoothing parameter — for smooths with multiple penalties, there will be multiple variance components). The `method` argument to `gam` selects the smoothness selection criterion.

Automatic smoothness selection is unlikely to be successful with few data, particularly with multiple terms to be selected. In addition GCV and UBRE/AIC score can occasionally display local minima that can trap the minimisation algorithms. GCV/UBRE/AIC scores become constant with changing smoothing parameters at very low or very high smoothing parameters, and on occasion these 'flat' regions can be separated from regions of lower score by a small 'lip'. This seems to be the most common form of local minimum, but is usually avoidable by avoiding extreme smoothing

parameters as starting values in optimization, and by avoiding big jumps in smoothing parameters while optimizing. Never the less, if you are suspicious of smoothing parameter estimates, try changing fit method (see `gam` arguments `method` and `optimizer`) and see if the estimates change, or try changing some or all of the smoothing parameters ‘manually’ (argument `sp` of `gam`, or `sp` arguments to `s` or `te`).

REML and ML are less prone to local minima than the other criteria, and may therefore be preferable.

### Automatic term selection

Unmodified smoothness selection by GCV, AIC, REML etc. will not usually remove a smooth from a model. This is because most smoothing penalties view some space of (non-zero) functions as ‘completely smooth’ and once a term is penalized heavily enough that it is in this space, further penalization does not change it.

However it is straightforward to modify smooths so that under heavy penalization they are penalized to the zero function and thereby ‘selected out’ of the model. There are two approaches.

The first approach is to modify the smoothing penalty with an additional shrinkage term. Smooth classes `cs.smooth` and `tps.smooth` (specified by “`cs`” and “`ts`” respectively) have smoothness penalties which include a small shrinkage component, so that for large enough smoothing parameters the smooth becomes identically zero. This allows automatic smoothing parameter selection methods to effectively remove the term from the model altogether. The shrinkage component of the penalty is set at a level that usually makes negligible contribution to the penalization of the model, only becoming effective when the term is effectively ‘completely smooth’ according to the conventional penalty.

The second approach leaves the original smoothing penalty unchanged, but constructs an additional penalty for each smooth, which penalizes only functions in the null space of the original penalty (the ‘completely smooth’ functions). Hence, if all the smoothing parameters for a term tend to infinity, the term will be selected out of the model. This latter approach is more expensive computationally, but has the advantage that it can be applied automatically to any smooth term. The `select` argument to `gam` turns on this method.

In fact, as implemented, both approaches operate by eigen-decomposing the original penalty matrix. A new penalty is created on the null space: it is the matrix with the same eigenvectors as the original penalty, but with the originally positive eigenvalues set to zero, and the originally zero eigenvalues set to something positive. The first approach just adds a multiple of this penalty to the original penalty, where the multiple is chosen so that the new penalty can not dominate the original. The second approach treats the new penalty as an extra penalty, with its own smoothing parameter.

Of course, as with all model selection methods, some care must be taken to ensure that the automatic selection is sensible, and a decision about the effective degrees of freedom at which to declare a term ‘negligible’ has to be made.

### Interactive term selection

In general the most logically consistent method to use for deciding which terms to include in the model is to compare GCV/UBRE/ML scores for models with and without the term (REML scores should not be used to compare models with different fixed effects structures). When UBRE is the smoothness selection method this will give the same result as comparing by AIC (the AIC in this case uses the model EDF in place of the usual model DF). Similarly, comparison via GCV score and via AIC seldom yields different answers. Note that the negative binomial with estimated `theta` parameter is a special case: the GCV score is not informative, because of the `theta` estimation scheme used. More generally the score for the model with a smooth term can be compared to the score for the model with the smooth term replaced by appropriate parametric terms. Candidates for

replacement by parametric terms are smooth terms with estimated degrees of freedom close to their minimum possible.

Candidates for removal can also be identified by reference to the approximate p-values provided by `summary.gam`, and by looking at the extent to which the confidence band for an estimated term includes the zero function. It is perfectly possible to perform backwards selection using p-values in the usual way: that is by sequentially dropping the single term with the highest non-significant p-value from the model and re-fitting, until all terms are significant. This suffers from the same problems as stepwise procedures for any GLM/LM, with the additional caveat that the p-values are only approximate. If adopting this approach, it is probably best to use ML smoothness selection.

Note that GCV and UBRE are not appropriate for comparing models using different families: in that case AIC should be used.

### Caveats/platitudes

Formal model selection methods are only appropriate for selecting between reasonable models. If formal model selection is attempted starting from a model that simply doesn't fit the data, then it is unlikely to provide meaningful results.

The more thought is given to appropriate model structure up front, the more successful model selection is likely to be. Simply starting with a hugely flexible model with 'everything in' and hoping that automatic selection will find the right structure is not often successful.

`gam.side`*Identifiability side conditions for a GAM*

---

### Description

GAM formulae with repeated variables only correspond to identifiable models given some side conditions. This routine works out appropriate side conditions, based on zeroing redundant parameters. It is called from `mgcv:::gam.setup` and is not intended to be called by users.

The method identifies nested and repeated variables by their names, but numerically evaluates which constraints need to be imposed. Constraints are always applied to smooths of more variables in preference to smooths of fewer variables. The numerical approach allows appropriate constraints to be applied to models constructed using any smooths, including user defined smooths.

### Usage

```
gam.side(sm, Xp, tol=.Machine$double.eps^.5)
```

### Arguments

<code>sm</code>	A list of smooth objects as returned by <code>smooth.construct</code> .
<code>Xp</code>	The model matrix for the strictly parametric model components.
<code>tol</code>	The tolerance to use when assessing linear dependence of smooths.

### Details

Models such as  $y \sim s(x) + s(z) + s(x, z)$  can be estimated by `gam`, but require identifiability constraints to be applied, to make them identifiable. This routine does this, effectively setting redundant parameters to zero. When the redundancy is between smooths of lower and higher numbers of variables, the constraint is always applied to the smooth of the higher number of variables.

Dependent smooths are identified symbolically, but which constraints are needed to ensure identifiability of these smooths is determined numerically, using `fixDependence`. This makes the routine rather general, and not dependent on any particular basis.

`Xp` is used to check whether there is a constant term in the model (or columns that can be linearly combined to give a constant). This is because centred smooths can appear independent, when they would be dependent if there is a constant in the model, so dependence testing needs to take account of this.

### Value

A list of smooths, with model matrices and penalty matrices adjusted to automatically impose the required constraints. Any smooth that has been modified will have an attribute `"del.index"`, listing the columns of its model matrix that were deleted. This index is used in the creation of prediction matrices for the term.

gam.vcomp

*Report gam smoothness estimates as variance components***Description**

GAMs can be viewed as mixed models, where the smoothing parameters are related to variance components. This routine extracts the estimated variance components associated with each smooth term, and if possible returns confidence intervals on the standard deviation scale.

**Usage**

```
gam.vcomp(x, rescale=TRUE, conf.lev=.95)
```

**Arguments**

<code>x</code>	a fitted model object of class <code>gam</code> as produced by <code>gam()</code> .
<code>rescale</code>	the penalty matrices for smooths are rescaled before fitting, for numerical stability reasons, if <code>rescale</code> this rescaling is reversed, so that the variance components are on the original scale.
<code>conf.lev</code>	when the smothing parameters are estimated by REML or ML, then confidence intervals for the variance components can be obtained from large sample likelihood results. This gives the confidence level to work at.

**Details**

The (pseudo) inverse of the penalty matrix penalizing a term is proportional to the covariance matrix of the term's coefficients, when these are viewed as random. For single penalty smooths, it is possible to compute the variance component for the smooth (which multiplies the inverse penalty matrix to obtain the covariance matrix of the smooth's coefficients). This variance component is given by the scale parameter divided by the smoothing parameter.

This routine computes such variance components, for `gam` models, and associated confidence intervals, if smoothing parameter estimation was likelihood based. Note that variance components are also returned for tensor product smooths, but that their interpretation is not so straightforward.

The routine is particularly useful for model fitted by `gam` in which random effects have been incorporated.

### Value

Either a vector of variance components for each smooth term (as standard deviations), or a matrix. The first column of the matrix gives standard deviations for each term, while the subsequent columns give lower and upper confidence bounds, on the same scale.

The routine prints a table of estimated standard deviations and confidence limits, if these can be computed, and reports the numerical rank of the covariance matrix.

`gam2objective`*Objective functions for GAM smoothing parameter estimation*

---

**Description**

Estimation of GAM smoothing parameters is most stable if optimization of the UBRE/AIC or GCV score is outer to the penalized iteratively re-weighted least squares scheme used to estimate the model given smoothing parameters. These functions evaluate the GCV/UBRE/AIC score of a GAM model, given smoothing parameters, in a manner suitable for use by `optim` or `nlm`. Not normally called directly, but rather service routines for `gam.outer`.

**Usage**

```
gam2objective(lsp, args, ...)  
gam2derivative(lsp, args, ...)
```

**Arguments**

<code>lsp</code>	The log smoothing parameters.
<code>args</code>	List of arguments required to call <code>gam.fit3</code> .
<code>...</code>	Other arguments for passing to <code>gam.fit3</code> .

**Details**

`gam2objective` and `gam2derivative` are functions suitable for calling by `optim`, to evaluate the GCV/UBRE/AIC score and its derivatives w.r.t. log smoothing parameters.

`gam4objective` is an equivalent to `gam2objective`, suitable for optimization by `nlm` - derivatives of the GCV/UBRE/AIC function are calculated and returned as attributes.

The basic idea of optimizing smoothing parameters ‘outer’ to the P-IRLS loop was first proposed in O’Sullivan et al. (1986).

`gam.fit3`, `gam`, `mgcv`, `magic`

## Description

Fits the specified generalized additive mixed model (GAMM) to data, by a call to `lme` in the normal errors identity link case, or by a call to `gammPQL` (a modification of `glmPQL` from the MASS library) otherwise. In the latter case estimates are only approximately MLEs. The routine is typically slower than `gam`, and not quite as numerically robust.

To use `lme4` in place of `nlme` as the underlying fitting engine, see `gamm4` from package `gamm4`.

Smooths are specified as in a call to `gam` as part of the fixed effects model formula, but the wiggly components of the smooth are treated as random effects. The random effects structures and correlation structures available for `lme` are used to specify other random effects and correlations.

It is assumed that the random effects and correlation structures are employed primarily to model residual correlation in the data and that the prime interest is in inference about the terms in the fixed effects model formula including the smooths. For this reason the routine calculates a posterior covariance matrix for the coefficients of all the terms in the fixed effects formula, including the smooths.

To use this function effectively it helps to be quite familiar with the use of `gam` and `lme`.

## Usage

```
gamm(formula, random=NULL, correlation=NULL, family=gaussian(),
      data=list(), weights=NULL, subset=NULL, na.action, knots=NULL,
      control=nlme::lmeControl(niterEM=0, optimMethod="L-BFGS-B"),
      niterPQL=20, verbosePQL=TRUE, method="ML", ...)
```

## Arguments

<code>formula</code>	A GAM formula (see also <code>formula.gam</code> and <code>gam.models</code> ). This is like the formula for a <code>glm</code> except that smooth terms ( <code>s</code> and <code>te</code> ) can be added to the right hand side of the formula. Note that <code>ids</code> for smooths and fixed smoothing parameters are not supported.
<code>random</code>	The (optional) random effects structure as specified in a call to <code>lme</code> : only the <code>list</code> form is allowed, to facilitate manipulation of the random effects structure within <code>gamm</code> in order to deal with smooth terms. See example below.
<code>correlation</code>	An optional <code>corStruct</code> object (see <code>corClasses</code> ) as used to define correlation structures in <code>lme</code> . Any grouping factors in the formula for this object are assumed to be nested within any random effect grouping factors, without the need to make this explicit in the formula (this is slightly different to the behaviour of <code>lme</code> ). See examples below.
<code>family</code>	A family as used in a call to <code>glm</code> or <code>gam</code> . The default <code>gaussian</code> with identity link causes <code>gamm</code> to fit by a direct call to <code>lme</code> provided there is no offset term, otherwise <code>gammPQL</code> is used.
<code>data</code>	A data frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from <code>environment(formula)</code> , typically the environment from which <code>gamm</code> is called.

<code>weights</code>	In the generalized case, weights with the same meaning as <code>glm</code> weights. An <code>lme</code> type weights argument may only be used in the identity link gaussian case, with no offset (see documentation for <code>lme</code> for details of how to use such an argument).
<code>subset</code>	an optional vector specifying a subset of observations to be used in the fitting process.
<code>na.action</code>	a function which indicates what should happen when the data contain 'NA's. The default is set by the 'na.action' setting of 'options', and is 'na.fail' if that is unset. The "factory-fresh" default is 'na.omit'.
<code>knots</code>	this is an optional list containing user specified knot values to be used for basis construction. Different terms can use different numbers of knots, unless they share a covariate.
<code>control</code>	A list of fit control parameters for <code>lme</code> returned by <code>lmeControl</code> . Note the default setting for the number of EM iterations used by <code>lme</code> : smooths are set up using custom <code>pdMat</code> classes, which are currently not supported by the EM iteration code. Only increase this number if you want to perturb the starting values used in model fitting (usually to worse values!). The <code>optimMethod</code> option is only used if your version of R does not have the <code>nlminb</code> optimizer function.
<code>niterPQL</code>	Maximum number of PQL iterations (if any).
<code>verbosePQL</code>	Should PQL report its progress as it goes along?
<code>method</code>	Which of "ML" or "REML" to use in the Gaussian additive mixed model case when <code>lme</code> is called directly. Ignored in the generalized case (or if the model has an offset), in which case <code>gammPQL</code> is used.
<code>...</code>	further arguments for passing on e.g. to <code>lme</code>

## Details

The Bayesian model of spline smoothing introduced by Wahba (1983) and Silverman (1985) opens up the possibility of estimating the degree of smoothness of terms in a generalized additive model as variances of the wiggly components of the smooth terms treated as random effects. Several authors have recognised this (see Wang 1998; Ruppert, Wand and Carroll, 2003) and in the normal errors, identity link case estimation can be performed using general linear mixed effects modelling software such as `lme`. In the generalized case only approximate inference is so far available, for example using the Penalized Quasi-Likelihood approach of Breslow and Clayton (1993) as implemented in `glmPQL` by Venables and Ripley (2002). One advantage of this approach is that it allows correlated errors to be dealt with via random effects or the correlation structures available in the `nlme` library.

Some details of how GAMs are represented as mixed models and estimated using `lme` or `gammPQL` in `gamm` can be found in Wood (2004, 2006a,b). In addition `gamm` obtains a posterior covariance matrix for the parameters of all the fixed effects and the smooth terms. The approach is similar to that described in Lin & Zhang (1999) - the covariance matrix of the data (or pseudodata in the generalized case) implied by the weights, correlation and random effects structure is obtained, based on the estimates of the parameters of these terms and this is used to obtain the posterior covariance matrix of the fixed and smooth effects.

The bases used to represent smooth terms are the same as those used in `gam`, although adaptive smoothing bases are not available.

In the event of `lme` convergence failures, consider modifying `option(mgcv.vc.logrange)`: reducing it helps to remove indefiniteness in the likelihood, if that is the problem, but too large a

reduction can force over or undersmoothing. See [notExp2](#) for more information on this option. Failing that, you can try increasing the `niterEM` option in `control`: this will perturb the starting values used in fitting, but usually to values with lower likelihood! Note that this version of `gamm` works best with R 2.2.0 or above and `nlme`, 3.1-62 and above, since these use an improved optimizer.

## Value

Returns a list with two items:

<code>gam</code>	an object of class <code>gam</code> , less information relating to GCV/UBRE model selection. At present this contains enough information to use <code>predict</code> , <code>summary</code> and <code>print</code> methods and <code>vis.gam</code> , but not to use e.g. the <code>anova</code> method function to compare models.
<code>lme</code>	the fitted model object returned by <code>lme</code> or <code>gammPQL</code> . Note that the model formulae and grouping structures may appear to be rather bizarre, because of the manner in which the GAMM is split up and the calls to <code>lme</code> and <code>gammPQL</code> are constructed.

## WARNINGS

`gamm` assumes that you know what you are doing! For example, unlike `glmPQL` from `MASS` it will return the complete `lme` object from the working model at convergence of the PQL iteration, including the ‘log likelihood’, even though this is not the likelihood of the fitted GAMM.

The routine will be very slow and memory intensive if correlation structures are used for the very large groups of data. e.g. attempting to run the spatial example in the examples section with many 1000’s of data is definitely not recommended: often the correlations should only apply within clusters that can be defined by a grouping factor, and provided these clusters do not get too huge then fitting is usually possible.

Models must contain at least one random effect: either a smooth with non-zero smoothing parameter, or a random effect specified in argument `random`.

`gamm` is not as numerically stable as `gam`: an `lme` call will occasionally fail. See details section for suggestions, or try the ‘`gamm4`’ package.

`gamm` is usually much slower than `gam`, and on some platforms you may need to increase the memory available to R in order to use it with large data sets (see [mem.limits](#)).

Note that the weights returned in the fitted GAM object are dummy, and not those used by the PQL iteration: this makes partial residual plots look odd.

Note that the `gam` object part of the returned object is not complete in the sense of having all the elements defined in [gamObject](#) and does not inherit from `glm`: hence e.g. multi-model `anova` calls will not work.

The parameterization used for the smoothing parameters in `gamm`, bounds them above and below by an effective infinity and effective zero. See [notExp2](#) for details of how to change this.

Linked smoothing parameters and adaptive smoothing are not supported.

```

gamObject

*Fitted gam object***Description**

A fitted GAM object returned by function `gam` and of class "gam" inheriting from classes "glm" and "lm". Method functions `anova`, `logLik`, `influence`, `plot`, `predict`, `print`, `residuals` and `summary` exist for this class.

All compulsory elements of "glm" and "lm" objects are present, but the fitting method for a GAM is different to a linear model or GLM, so that the elements relating to the QR decomposition of the model matrix are absent.

**Value**

A gam object has the following elements:

<code>aic</code>	AIC of the fitted model: bear in mind that the degrees of freedom used to calculate this are the effective degrees of freedom of the model, and the likelihood is evaluated at the maximum of the penalized likelihood in most cases, not at the MLE.
<code>assign</code>	Array whose elements indicate which model term (listed in <code>pterms</code> ) each parameter relates to: applies only to non-smooth terms.
<code>boundary</code>	did parameters end up at boundary of parameter space?

<code>call</code>	the matched call (allows <code>update</code> to be used with <code>gam</code> objects, for example).
<code>cmX</code>	column means of the model matrix (with elements corresponding to smooths set to zero) — useful for componentwise CI calculation.
<code>coefficients</code>	the coefficients of the fitted model. Parametric coefficients are first, followed by coefficients for each spline term in turn.
<code>control</code>	the <code>gam</code> control list used in the fit.
<code>converged</code>	indicates whether or not the iterative fitting method converged.
<code>data</code>	the original supplied data argument (for class "glm" compatibility). Only included if <code>gam</code> control argument element <code>keepData</code> is set to <code>TRUE</code> (default is <code>FALSE</code> ).
<code>deviance</code>	model deviance (not penalized deviance).
<code>df.null</code>	null degrees of freedom.
<code>df.residual</code>	effective residual degrees of freedom of the model.
<code>edf</code>	estimated degrees of freedom for each model parameter. Penalization means that many of these are less than 1.
<code>edf1</code>	similar, but using alternative estimate of EDF. Useful for testing.
<code>family</code>	family object specifying distribution and link used.
<code>fitted.values</code>	fitted model predictions of expected value for each datum.
<code>formula</code>	the model formula.
<code>full.sp</code>	full array of smoothing parameters multiplying penalties (excluding any contribution from <code>min.sp</code> argument to <code>gam</code> ). May be larger than <code>sp</code> if some terms share smoothing parameters, and/or some smoothing parameter values were supplied in the <code>sp</code> argument of <code>gam</code> .
<code>gcv.ubre</code>	The minimized smoothing parameter selection score: GCV, UBRE(AIC), GACV, negative log marginal likelihood or negative log restricted likelihood.
<code>hat</code>	array of elements from the leading diagonal of the 'hat' (or 'influence') matrix. Same length as response data vector.
<code>iter</code>	number of iterations of P-IRLS taken to get convergence.
<code>linear.predictors</code>	fitted model prediction of link function of expected value for each datum.
<code>method</code>	One of "GCV" or "UBRE", "REML", "P-REML", "ML", "P-ML", "PQL", "lme.ML" or "lme.REML", depending on the fitting criterion used.
<code>mgcv.conv</code>	A list of convergence diagnostics relating to the "magic" parts of smoothing parameter estimation - this will not be very meaningful for pure "outer" estimation of smoothing parameters. The items are: <code>full.rank</code> , The apparent rank of the problem given the model matrix and constraints; <code>rank</code> , The numerical rank of the problem; <code>fully.converged</code> , TRUE is multiple GCV/UBRE converged by meeting convergence criteria and FALSE if method stopped with a steepest descent step failure; <code>hess.pos.def</code> Was the hessian of the GCV/UBRE score positive definite at smoothing parameter estimation convergence?; <code>iter</code> How many iterations were required to find the smoothing parameters? <code>score.calls</code> , and how many times did the GCV/UBRE score have to be evaluated?; <code>rms.grad</code> , root mean square of the gradient of the GCV/UBRE score at convergence.
<code>min.edf</code>	Minimum possible degrees of freedom for whole model.

<code>model</code>	model frame containing all variables needed in original model fit.
<code>na.action</code>	The <code>na.action</code> used in fitting.
<code>nsdf</code>	number of parametric, non-smooth, model terms including the intercept.
<code>null.deviance</code>	deviance for single parameter model.
<code>offset</code>	model offset.
<code>optimizer</code>	optimizer argument to <code>gam</code> , or "magic" if it's a pure additive model.
<code>outer.info</code>	If 'outer' iteration has been used to fit the model (see <code>gam</code> argument <code>optimizer</code> ) then this is present and contains whatever was returned by the optimization routine used (currently <code>nlm</code> or <code>optim</code> ).
<code>prior.weights</code>	prior weights on observations.
<code>pterms</code>	terms object for strictly parametric part of model.
<code>rank</code>	apparent rank of fitted model.
<code>reml.scale</code>	The scale (RE)ML scale parameter estimate, if (P-)(RE)ML used for smoothness estimation.
<code>residuals</code>	the working residuals for the fitted model.
<code>scale</code>	when present, the scale (as <code>sig2</code> )
<code>scale.estimated</code>	TRUE if the scale parameter was estimated, FALSE otherwise.
<code>sig2</code>	estimated or supplied variance/scale parameter.
<code>smooth</code>	list of smooth objects, containing the basis information for each term in the model formula in the order in which they appear. These smooth objects are what gets returned by the <code>smooth.construct</code> objects.
<code>sp</code>	estimated smoothing parameters for the model. These are the underlying smoothing parameters, subject to optimization. For the full set of smoothing parameters multiplying the penalties see <code>full.sp</code> . Divide the scale parameter by the smoothing parameters to get, variance components, but note that this is not valid for smooths that have used rescaling to improve conditioning.
<code>terms</code>	terms object of model model frame.
<code>var.summary</code>	A named list of summary information on the predictor variables. If a parametric variable is a matrix, then the summary is a one row matrix, containing the observed data value closest to the column median, for each matrix column. If the variable is a factor then the summary is the modal factor level, returned as a factor, with levels corresponding to those of the data. For numerics and matrix arguments of smooths, the summary is the mean, nearest observed value to median and maximum, as a numeric vector. Used by <code>vis.gam</code> , in particular.
<code>Ve</code>	frequentist estimated covariance matrix for the parameter estimators. Particularly useful for testing whether terms are zero. Not so useful for CI's as smooths are usually biased.
<code>Vp</code>	estimated covariance matrix for the parameters. This is a Bayesian posterior covariance matrix that results from adopting a particular Bayesian model of the smoothing process. Particularly useful for creating credible/confidence intervals.
<code>weights</code>	final weights used in IRLS iteration.
<code>y</code>	response data.

## WARNINGS

This model object is different to that described in Chambers and Hastie (1993) in order to allow smoothing parameter estimation etc.

---

gamSim

*Simulate example data for GAMs*

---

## Description

Function used to simulate data sets to illustrate the use of [gam](#) and [gamm](#). Mostly used in help files to keep down the length of the example code sections.

## Usage

```
gamSim(eg=1, n=400, dist="normal", scale=2)
```

## Arguments

eg	numeric value specifying the example required.
n	number of data to simulate.
dist	character string which may be used to specify the distribution of the response.
scale	Used to set noise level.

## Details

See the source code for exactly what is simulated in each case.

1. Gu and Wahba 4 univariate term example.
2. A smooth function of 2 variables.
3. Example with continuous by variable.
4. Example with factor by variable.
5. An additive example plus a factor variable.
6. Additive + random effect.
7. As 1 but with correlated covariates.

**Value**

Depends on `eg`, but usually a dataframe, which may also contain some information on the underlying truth. Sometimes a list with more items, including a data frame for model fitting. See source code or helpfile examples where the function is used for further information.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

```

---

`get.var`

*Get named variable or evaluate expression from list or data.frame*

---

**Description**

This routine takes a text string and a data frame or list. It first sees if the string is the name of a variable in the data frame/ list. If it is then the value of this variable is returned. Otherwise the routine tries to evaluate the expression within the data.frame/list (but nowhere else) and if successful returns the result. If neither step works then `NULL` is returned. The routine is useful for processing gam formulae. If the variable is a matrix then it is coerced to a numeric vector, by default.

**Usage**

```
get.var(txt, data, vecMat=TRUE)
```

**Arguments**

<code>txt</code>	a text string which is either the name of a variable in <code>data</code> or when parsed is an expression that can be evaluated in <code>data</code> . It can also be neither in which case the function returns <code>NULL</code> .
<code>data</code>	A data frame or list.
<code>vecMat</code>	Should matrices be coerced to numeric vectors?

**Value**

The evaluated variable or `NULL`. May be coerced to a numeric vector if it's a matrix.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**References**

<http://www.maths.bath.ac.uk/~sw283/>

```
y <- 1:4; dat<-data.frame(x=5:10)
get.var("x", dat)
get.var("y", dat)
get.var("x==6", dat)
dat <- list(X=matrix(1:6,3,2))
get.var("X", dat)
```

---

`influence.gam`*Extract the diagonal of the influence/hat matrix for a GAM*

---

**Description**

Extracts the leading diagonal of the influence matrix (hat matrix) of a fitted `gam` object.

**Usage**

```
## S3 method for class 'gam':
influence(model, ...)
```

**Arguments**

<code>model</code>	fitted model objects of class <code>gam</code> as produced by <code>gam()</code> .
<code>...</code>	un-used in this case

**Details**

Simply extracts `hat` array from fitted model. (More may follow!)

**Value**

An array (see above).

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**See Also**[gam](#)

---

`initial.sp`*Starting values for multiple smoothing parameter estimation*

---

### Description

Finds initial smoothing parameter guesses for multiple smoothing parameter estimation. The idea is to find values such that the estimated degrees of freedom per penalized parameter should be well away from 0 and 1 for each penalized parameter, thus ensuring that the values are in a region of parameter space where the smoothing parameter estimation criterion is varying substantially with smoothing parameter value.

### Usage

```
initial.sp(X, S, off, expensive=FALSE)
```

### Arguments

<code>X</code>	is the model matrix.
<code>S</code>	is a list of of penalty matrices. <code>S[[i]]</code> is the <i>i</i> th penalty matrix, but note that it is not stored as a full matrix, but rather as the smallest square matrix including all the non-zero elements of the penalty matrix. Element 1,1 of <code>S[[i]]</code> occupies element <code>off[i], off[i]</code> of the <i>i</i> th penalty matrix. Each <code>S[[i]]</code> must be positive semi-definite.
<code>off</code>	is an array indicating the first parameter in the parameter vector that is penalized by the penalty involving <code>S[[i]]</code> .
<code>expensive</code>	if <code>TRUE</code> then the overall amount of smoothing is adjusted so that the average degrees of freedom per penalized parameter is exactly 0.5: this is numerically costly.

### Details

Basically uses a crude approximation to the estimated degrees of freedom per model coefficient, to try and find smoothing parameters which bound these e.d.f.'s away from 0 and 1.

Usually only called by `magic` and `gam`.

### Value

An array of initial smoothing parameter estimates.

### Author(s)

Simon N. Wood <simon.wood@r-project.org>

### See Also

`magic`, `gam.outer`, `gam`,

---

interpret.gam      *Interpret a GAM formula*

---

### Description

This is an internal function of package `mgcv`. It is a service routine for `gam` which splits off the strictly parametric part of the model formula, returning it as a formula, and interprets the smooth parts of the model formula.

Not normally called directly.

### Usage

```
interpret.gam(gf)
```

### Arguments

`gf`                    A GAM formula as supplied to `gam` or `gamm`.

### Value

An object of class `split.gam.formula` with the following items:

`pf`                    A model formula for the strictly parametric part of the model.

`pfok`                 TRUE if there is a `pf` formula.

`smooth.spec`        A list of class `xx.smooth.spec` objects where `xx` depends on the basis specified for the term. (These can be passed to smooth constructor method functions to actually set up penalties and bases.)

`full.formula`        An expanded version of the model formula in which the options are fully expanded, and the options do not depend on variables which might not be available later.

`fake.formula`        A formula suitable for use in evaluating a model frame.

`response`            Name of the response variable.

ldTweedie

*Log Tweedie density evaluation***Description**

A function to evaluate the log of the Tweedie density for variance powers between 1 and 2, inclusive. Also evaluates first and second derivatives of log density w.r.t. its scale parameter.

**Usage**

```
ldTweedie(y, mu=y, p=1.5, phi=1)
```

**Arguments**

y	values at which to evaluate density.
mu	corresponding means (either of same length as y or a single value).
p	the variance of y is proportional to its mean to the power p. p must be between 1 and 2. 1 is Poisson like (exactly Poisson if phi=1), 2 is gamma.
phi	The scale parameter. Variance of y is phi*mu^p.

**Details**

A Tweedie random variable with  $1 < p < 2$  is a sum of  $N$  gamma random variables where  $N$  has a Poisson distribution. The  $p=1$  case is a generalization of a Poisson distribution and is a discrete distribution supported on integer multiples of the scale parameter. For  $1 < p < 2$  the distribution is supported on the positive reals with a point mass at zero.  $p=2$  is a gamma distribution. As  $p$  gets very close to 1 the continuous distribution begins to converge on the discretely supported limit at  $p=1$ .

ldTweedie is based on the series evaluation method of Dunn and Smyth (2005). Without the restriction on  $p$  the calculation of Tweedie densities is less straightforward. If you really need this case then the `tweedie` package is the place to start.

**Value**

A matrix with 3 columns. The first is the log density of y (log probability if  $p=1$ ). The second and third are the first and second derivatives of the log density w.r.t. phi.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org> modified from Venables and Ripley's `negative.binomial` family.

*Linear functionals of a smooth in GAMs*

---

**Description**

`gam` allows the response variable to depend on linear functionals of smooth terms. Specifically dependencies of the form

$$g(\mu_i) = \dots + \sum_j L_{ij} f(x_{ij}) + \dots$$

are allowed, where the  $x_{ij}$  are covariate values and the  $L_{ij}$  are fixed weights. i.e. the response can depend on the weighted sum of the same smooth evaluated at different covariate values. This allows, for example, for the response to depend on the derivatives or integrals of a smooth (approximated by finite differencing or quadrature, respectively). It also allows dependence on predictor functions (sometimes called ‘signal regression’).

The mechanism by which this is achieved is to supply matrices of covariate values to the model smooth terms specified by `s` or `te` terms in the model formula. Each column of the covariate matrix gives rise to a corresponding column of predictions from the smooth. Let the resulting matrix of evaluated smooth values be  $F$  ( $F$  will have the same dimension as the covariate matrices). In the absence of a `by` variable then these columns are simply summed and added to the linear predictor. i.e. the contribution of the term to the linear predictor is `rowSums(F)`. If a `by` variable is present then it must be a matrix,  $L$ , say, of the same dimension as  $F$  (and the covariate matrices), and it contains the weights  $L_{ij}$  in the summation given above. So in this case the contribution to the linear predictor is `rowSums(L*F)`.

Note that if a  $L\mathbf{1}$  (i.e. `rowSums(L)`) is a constant vector, or there is no `by` variable then the smooth will automatically be centred in order to ensure identifiability. Otherwise it will not be. Note also that for centred smooths it can be worth replacing the constant term in the model with `rowSums(L)` in order to ensure that predictions are automatically on the right scale.

When predicting from the model it is not necessary to provide matrix covariate and `by` variable values. For example to simply examine the underlying smooth function one would use vectors of covariate values and vector `by` variables, with the `by` variable and equivalent of  $L\mathbf{1}$ , above, set to vectors of ones.

plot(b,shade=TRUE);lines(x,f,col=2)

```

---

logLik.gam

---

*Extract the log likelihood for a fitted GAM*

---

## Description

Function to extract the log-likelihood for a fitted `gam` model (note that the models are usually fitted by penalized likelihood maximization).

## Usage

```
## S3 method for class 'gam':
logLik(object, ...)
```

## Arguments

<code>object</code>	fitted model objects of class <code>gam</code> as produced by <code>gam()</code> .
<code>...</code>	un-used in this case

## Details

Modification of `logLik.glm` which corrects the degrees of freedom for use with `gam` objects.

The function is provided so that [AIC](#) functions correctly with `gam` objects, and uses the appropriate degrees of freedom (accounting for penalization). Note, when using [AIC](#) for penalized models, that the degrees of freedom are the effective degrees of freedom and not the number of parameters, and the model maximizes the penalized likelihood, not the actual likelihood! This seems to be reasonably well founded for the known scale parameter case (see Hastie and Tibshirani, 1990, section 6.8.3 and also Wood 2008), and in fact in this case the default smoothing parameter estimation criterion is effectively this modified [AIC](#).

**Value**

Standard logLik object: see [logLik](#).

ls.size

*Size of list elements*

---

**Description**

Produces a named array giving the size, in bytes, of the elements of a list.

**Usage**

```
ls.size(x)
```

**Arguments**

x                    A list.

**Details**

A numeric vector giving the size in bytes of each element of the list x. The elements of the array have the same names as the elements of the list. If x is not a list then its size in bytes is returned, un-named.

**Value**

An object of class "gam" as described in [gamObject](#).

"The world is ruled by idiots because only an idiot would want to rule the world.",
fam=binomial())
ls.size(b)
```

magic

*Stable Multiple Smoothing Parameter Estimation by GCV or UBRE,  
with optional fixed penalty*

**Description**

Function to efficiently estimate smoothing parameters in generalized ridge regression problems with multiple (quadratic) penalties, by GCV or UBRE. The function uses Newton's method in multi-dimensions, backed up by steepest descent to iteratively adjust the smoothing parameters for each penalty (one penalty may have a smoothing parameter fixed at 1).

For maximal numerical stability the method is based on orthogonal decomposition methods, and attempts to deal with numerical rank deficiency gracefully using a truncated singular value decomposition approach.

**Usage**

```
magic(y, X, sp, S, off, L=NULL, lsp0=NULL, rank=NULL, H=NULL, C=NULL,
w=NULL, gamma=1, scale=1, gcv=TRUE, ridge.parameter=NULL,
control=list(maxit=50, tol=1e-6, step.half=25,
rank.tol=.Machine$double.eps^0.5), extra.rss=0, n.score=length(y))
```

**Arguments**

- |     |   |
|-----|---|
| y   | is the response data vector.  |
| X   | is the model matrix.  |
| sp  | is the array of smoothing parameters. The vector $L \times \log(sp) + lsp0$ contains the logs of the smoothing parameters that actually multiply the penalty matrices stored in S (L is taken as the identity if NULL). Any sp values that are negative are autoinitialized, otherwise they are taken as supplying starting values. A supplied starting value will be reset to a default starting value if the gradient of the GCV/UBRE score is too small at the supplied value. |
| S   | is a list of of penalty matrices. $S[[i]]$ is the <i>i</i> th penalty matrix, but note that it is not stored as a full matrix, but rather as the smallest square matrix including all the non-zero elements of the penalty matrix. Element 1,1 of $S[[i]]$ occupies element $off[i], off[i]$ of the <i>i</i> th penalty matrix. Each $S[[i]]$ must be positive semi-definite. Set to <code>list()</code> if there are no smoothing parameters to be estimated.                    |
| off | is an array indicating the first parameter in the parameter vector that is penalized by the penalty involving $S[[i]]$ .  |
| L   | is a matrix mapping $\log(sp)$ to the log smoothing parameters that actually multiply the penalties defined by the elems of S. Taken as the identity, if NULL. See above under sp.  |

<code>lsp0</code>	If <code>L</code> is not <code>NULL</code> this is a vector of constants in the linear transformation from <code>log(sp)</code> to the actual log smoothing parameters. So the logs of the smoothing parameters multiplying the <code>S[[i]]</code> are given by <code>L%%log(sp) + lsp0</code> . Taken as 0 if <code>NULL</code> .
<code>rank</code>	is an array specifying the ranks of the penalties. This is useful, but not essential, for forming square roots of the penalty matrices.
<code>H</code>	is the optional offset penalty - i.e. a penalty with a smoothing parameter fixed at 1. This is useful for allowing regularization of the estimation process, fixed smoothing penalties etc.
<code>C</code>	is the optional matrix specifying any linear equality constraints on the fitting problem. If <code>b</code> is the parameter vector then the parameters are forced to satisfy $\mathbf{Cb} = \mathbf{0}$ .
<code>w</code>	the regression weights. If this is a matrix then it is taken as being the square root of the inverse of the covariance matrix of $\mathbf{y}$ , specifically $\mathbf{V}_y^{-1} = \mathbf{w}'\mathbf{w}$ . If <code>w</code> is an array then it is taken as the diagonal of this matrix, or simply the weight for each element of $\mathbf{y}$ . See below for an example using this.
<code>gamma</code>	is an inflation factor for the model degrees of freedom in the GCV or UBRE score.
<code>scale</code>	is the scale parameter for use with UBRE.
<code>gcv</code>	should be set to <code>TRUE</code> if GCV is to be used, <code>FALSE</code> for UBRE.
<code>ridge.parameter</code>	It is sometimes useful to apply a ridge penalty to the fitting problem, penalizing the parameters in the constrained space directly. Setting this parameter to a value greater than zero will cause such a penalty to be used, with the magnitude given by the parameter value.
<code>control</code>	is a list of iteration control constants with the following elements: <b>maxit</b> The maximum number of iterations of the magic algorithm to allow. <b>tol</b> The tolerance to use in judging convergence. <b>step.half</b> If a trial step fails then the method tries halving it up to a maximum of <code>step.half</code> times. <b>rank.tol</b> is a constant used to test for numerical rank deficiency of the problem. Basically any singular value less than <code>rank_tol</code> multiplied by the largest singular value of the problem is set to zero.
<code>extra.rss</code>	is a constant to be added to the residual sum of squares (squared norm) term in the calculation of the GCV, UBRE and scale parameter estimate. In conjunction with <code>n.score</code> , this is useful for certain methods for dealing with very large data sets.
<code>n.score</code>	number to use as the number of data in GCV/UBRE score calculation: usually the actual number of data, but there are methods for dealing with very large datasets that change this.

## Details

The method is a computationally efficient means of applying GCV or UBRE (often approximately AIC) to the problem of smoothing parameter selection in generalized ridge regression problems of the form:

$$\text{minimise } \|\mathbf{W}(\mathbf{Xb} - \mathbf{y})\|^2 + \mathbf{b}'\mathbf{Hb} + \sum_{i=1}^m \theta_i \mathbf{b}'\mathbf{S}_i \mathbf{b}$$

possibly subject to constraints  $\mathbf{Cb} = \mathbf{0}$ .  $\mathbf{X}$  is a design matrix,  $\mathbf{b}$  a parameter vector,  $\mathbf{y}$  a data vector,  $\mathbf{W}$  a weight matrix,  $\mathbf{S}_i$  a positive semi-definite matrix of coefficients defining the  $i$ th penalty with associated smoothing parameter  $\theta_i$ ,  $\mathbf{H}$  is the positive semi-definite offset penalty matrix and  $\mathbf{C}$  a matrix of coefficients defining any linear equality constraints on the problem.  $\mathbf{X}$  need not be of full column rank.

The  $\theta_i$  are chosen to minimize either the GCV score:

$$V_g = \frac{n \|\mathbf{W}(\mathbf{y} - \mathbf{A}\mathbf{y})\|^2}{[\text{tr}(\mathbf{I} - \gamma\mathbf{A})]^2}$$

or the UBRE score:

$$V_u = \|\mathbf{W}(\mathbf{y} - \mathbf{A}\mathbf{y})\|^2/n - 2\phi \text{tr}(\mathbf{I} - \gamma\mathbf{A})/n + \phi$$

where  $\gamma$  is gamma the inflation factor for degrees of freedom (usually set to 1) and  $\phi$  is `scale`, the scale parameter.  $\mathbf{A}$  is the hat matrix (influence matrix) for the fitting problem (i.e the matrix mapping data to fitted values). Dependence of the scores on the smoothing parameters is through  $\mathbf{A}$ .

The method operates by Newton or steepest descent updates of the logs of the  $\theta_i$ . A key aspect of the method is stable and economical calculation of the first and second derivatives of the scores w.r.t. the log smoothing parameters. Because the GCV/UBRE scores are flat w.r.t. very large or very small  $\theta_i$ , it's important to get good starting parameters, and to be careful not to step into a flat region of the smoothing parameter space. For this reason the algorithm rescales any Newton step that would result in a  $\log(\theta_i)$  change of more than 5. Newton steps are only used if the Hessian of the GCV/UBRE is positive definite, otherwise steepest descent is used. Similarly steepest descent is used if the Newton step has to be contracted too far (indicating that the quadratic model underlying Newton is poor). All initial steepest descent steps are scaled so that their largest component is 1. However a step is calculated, it is never expanded if it is successful (to avoid flat portions of the objective), but steps are successively halved if they do not decrease the GCV/UBRE score, until they do, or the direction is deemed to have failed. (Given the smoothing parameters the optimal  $\mathbf{b}$  parameters are easily found.)

The method is coded in C with matrix factorizations performed using LINPACK and LAPACK routines.

## Value

The function returns a list with the following items:

<code>b</code>	The best fit parameters given the estimated smoothing parameters.
<code>scale</code>	the estimated (GCV) or supplied (UBRE) scale parameter.
<code>score</code>	the minimized GCV or UBRE score.
<code>sp</code>	an array of the estimated smoothing parameters.
<code>sp.full</code>	an array of the smoothing parameters that actually multiply the elements of <code>S</code> (same as <code>sp</code> if <code>L</code> was <code>NULL</code> ). This is $\exp(L \cdot \log(sp))$ .
<code>rV</code>	a factored form of the parameter covariance matrix. The (Bayesian) covariance matrix of the parameters <code>b</code> is given by $rV \%*\%t(rV) * scale$ .
<code>gcv.info</code>	is a list of information about the performance of the method with the following elements: <b>full.rank</b> The apparent rank of the problem: number of parameters less number of equality constraints.

**rank** The estimated actual rank of the problem (at the final iteration of the method).

**fully.converged** is TRUE if the method converged by satisfying the convergence criteria, and FALSE if it covered by failing to decrease the score along the search direction.

**hess.pos.def** is TRUE if the hessian of the UBRE or GCV score was positive definite at convergence.

**iter** is the number of Newton/Steepest descent iterations taken.

**score.calls** is the number of times that the GCV/UBRE score had to be evaluated.

**rms.grad** is the root mean square of the gradient of the UBRE/GCV score w.r.t. the smoothing parameters.

Note that some further useful quantities can be obtained using [magic.post.proc](#).

---

magic.post.proc      *Auxilliary information from magic fit*

---

## Description

Obtains Bayesian parameter covariance matrix, frequentist parameter estimator covariance matrix, estimated degrees of freedom for each parameter and leading diagonal of influence/hat matrix, for a penalized regression estimated by `magic`.

## Usage

```
magic.post.proc(X, object, w)
```

## Arguments

<code>X</code>	is the model matrix.
<code>object</code>	is the list returned by <code>magic</code> after fitting the model with model matrix <code>X</code> .
<code>w</code>	is the weight vector used in fitting, or the weight matrix used in fitting (i.e. supplied to <code>magic</code> , if one was.). If <code>w</code> is a vector then its elements are typically proportional to reciprocal variances (but could even be negative). If <code>w</code> is a matrix then <code>t(w) %*% w</code> should typically give the inverse of the covariance matrix of the response data supplied to <code>magic</code> .

## Details

`object` contains  $rV(\mathbf{V}, \text{say})$ , and  $\text{scale}(\phi, \text{say})$  which can be used to obtain the require quantities as follows. The Bayesian covariance matrix of the parameters is  $\mathbf{V}\mathbf{V}'\phi$ . The vector of estimated degrees of freedom for each parameter is the leading diagonal of  $\mathbf{V}\mathbf{V}'\mathbf{X}'\mathbf{W}'\mathbf{W}\mathbf{X}$  where  $\mathbf{W}$  is either the weight matrix `w` or the matrix `diag(w)`. The hat/influence matrix is given by  $\mathbf{W}\mathbf{X}\mathbf{V}\mathbf{V}'\mathbf{X}'\mathbf{W}'$ .

The frequentist parameter estimator covariance matrix is  $\mathbf{V}\mathbf{V}'\mathbf{X}'\mathbf{W}'\mathbf{W}\mathbf{X}\mathbf{V}\mathbf{V}'\phi$ : it is sometimes useful for testing terms for equality to zero.

### Value

A list with three items:

<code>Vb</code>	the Bayesian covariance matrix of the model parameters.
<code>Ve</code>	the frequentist covariance matrix for the parameter estimators.
<code>hat</code>	the leading diagonal of the hat (influence) matrix.
<code>edf</code>	the array giving the estimated degrees of freedom associated with each parameter.

mgcv

*Multiple Smoothing Parameter Estimation by GCV or UBRE*

---

### Description

Function to efficiently estimate smoothing parameters in Generalized Ridge Regression Problem with multiple (quadratic) penalties, by GCV or UBRE. The function uses Newton's method in multi-dimensions, backed up by steepest descent to iteratively adjust a set of relative smoothing parameters for each penalty. To ensure that the overall level of smoothing is optimal, and to guard against trapping by local minima, a highly efficient global minimisation with respect to one overall smoothing parameter is also made at each iteration. This is the original Wood (2000) method. It has now been superceded by the methods in [magic](#) (Wood, 2004) and [gam.fit3](#) (Wood, 2008).

For a listing of all routines in the `mgcv` package type:

```
library(help="mgcv"). For an overview of the mgcv package see mgcv-package.
```

### Usage

```
mgcv(y, X, sp, S, off, C=NULL, w=rep(1, length(y)), H=NULL,
      scale=1, gcv=TRUE, control=mgcv.control())
```

### Arguments

<code>y</code>	The response data vector.
<code>X</code>	The design matrix for the problem, note that <code>ncol(X)</code> must give the number of model parameters, while <code>nrow(X)</code> should give the number of data.
<code>sp</code>	An array of smoothing parameters. If <code>control\$fixed==TRUE</code> then these are taken as being the smoothing parameters. Otherwise any positive values are assumed to be initial estimates and negative values to signal auto-initialization.

<code>S</code>	A list of penalty matrices. Only the smallest square block containing all non-zero matrix elements is actually stored, and <code>off[i]</code> indicates the element of the parameter vector that <code>S[[i]][1,1]</code> relates to.
<code>off</code>	Offset values indicating where in the overall parameter a particular stored penalty starts operating. For example if <code>p</code> is the model parameter vector and <code>k=nrow(S[[i]])-1</code> , then the <i>i</i> th penalty is given by <code>t(p[off[i]:(off[i]+k)])%*%S[[i]]%*%p[off[i]:(off[i]+k)]</code> .
<code>C</code>	Matrix containing any linear equality constraints on the problem (i.e. $\mathbf{C}\mathbf{p} = \mathbf{0}$ ).
<code>w</code>	A vector of weights for the data (often proportional to the reciprocal of the standard deviation of $\bar{y}$ ).
<code>H</code>	A single fixed penalty matrix to be used in place of the multiple penalty matrices in <code>S</code> . <code>mgcv</code> cannot mix fixed and estimated penalties.
<code>scale</code>	This is the known scale parameter/error variance to use with UBRE. Note that it is assumed that the variance of $y_i$ is given by $\sigma^2/w_i$ .
<code>gcv</code>	If <code>gcv</code> is TRUE then smoothing parameters are estimated by GCV, otherwise UBRE is used.
<code>control</code>	A list of control options returned by <code>mgcv.control</code> .

## Details

This is documentation for the code implementing the method described in section 4 of Wood (2000). The method is a computationally efficient means of applying GCV to the problem of smoothing parameter selection in generalized ridge regression problems of the form:

$$\text{minimise } \|\mathbf{W}(\mathbf{X}\mathbf{p} - \mathbf{y})\|^2 \rho + \sum_{i=1}^m \lambda_i \mathbf{p}' \mathbf{S}_i \mathbf{p}$$

possibly subject to constraints  $\mathbf{C}\mathbf{p} = \mathbf{0}$ .  $\mathbf{X}$  is a design matrix,  $\mathbf{p}$  a parameter vector,  $\mathbf{y}$  a data vector,  $\mathbf{W}$  a diagonal weight matrix,  $\mathbf{S}_i$  a positive semi-definite matrix of coefficients defining the *i*th penalty and  $\mathbf{C}$  a matrix of coefficients defining any linear equality constraints on the problem. The smoothing parameters are the  $\lambda_i$  but there is an overall smoothing parameter  $\rho$  as well. Note that  $\mathbf{X}$  must be of full column rank, at least when projected into the null space of any equality constraints.

The method operates by alternating very efficient direct searches for  $\rho$  with Newton or steepest descent updates of the logs of the  $\lambda_i$ . Because the GCV/UBRE scores are flat w.r.t. very large or very small  $\lambda_i$ , it's important to get good starting parameters, and to be careful not to step into a flat region of the smoothing parameter space. For this reason the algorithm rescales any Newton step that would result in a  $\log(\lambda_i)$  change of more than 5. Newton steps are only used if the Hessian of the GCV/UBRE is positive definite, otherwise steepest descent is used. Similarly steepest descent is used if the Newton step has to be contracted too far (indicating that the quadratic model underlying Newton is poor). All initial steepest descent steps are scaled so that their largest component is 1. However a step is calculated, it is never expanded if it is successful (to avoid flat portions of the objective), but steps are successively halved if they do not decrease the GCV/UBRE score, until they do, or the direction is deemed to have failed. `M$conv` provides some convergence diagnostics.

The method is coded in C and is intended to be portable. It should be noted that seriously ill conditioned problems (i.e. with close to column rank deficiency in the design matrix) may cause problems, especially if weights vary wildly between observations.

**Value**

An object is returned with the following elements:

<code>b</code>	The best fit parameters given the estimated smoothing parameters.
<code>scale</code>	The estimated or supplied scale parameter/error variance.
<code>score</code>	The UBRE or GCV score.
<code>sp</code>	The estimated (or supplied) smoothing parameters ( $\lambda_i/\rho$ )
<code>Vb</code>	Estimated covariance matrix of model parameters.
<code>hat</code>	diagonal of the hat/influence matrix.
<code>edf</code>	array of estimated degrees of freedom for each parameter.
<code>info</code>	A list of convergence diagnostics, with the following elements: <b>edf</b> Array of whole model estimated degrees of freedom. <b>score</b> Array of ubre/gcv scores at the edfs for the final set of relative smoothing parameters. <b>g</b> the gradient of the GCV/UBRE score w.r.t. the smoothing parameters at termination. <b>h</b> the second derivatives corresponding to <code>g</code> above - i.e. the leading diagonal of the Hessian. <b>e</b> the eigenvalues of the Hessian. These should all be non-negative! <b>iter</b> the number of iterations taken. <b>in.ok</b> TRUE if the second smoothing parameter guess improved the GCV/UBRE score. (Please report examples where this is FALSE) <b>step.fail</b> TRUE if the algorithm terminated by failing to improve the GCV/UBRE score rather than by "converging". Not necessarily a problem, but check the above derivative information quite carefully.

**WARNING**

The method may not behave well with near column rank deficient **X** especially in contexts where the weights vary wildly.

mgcv.control

*Setting mgcv defaults*

---

**Description**

This is an internal function of package `mgcv` which allows control of the numerical options for fitting a generalized ridge regression problem using routine `mgcv`.

**Usage**

```
mgcv.control(conv.tol=1e-7,max.half=20,target.edf=NULL,min.edf=-1)
```

**Arguments**

<code>conv.tol</code>	The convergence tolerance.
<code>max.half</code>	successive step halvings are employed if the Newton method and then the steepest descent backup fail to improve the UBRE/GCV score. This is how many to use before giving up.
<code>target.edf</code>	If this is non-null it indicates that cautious optimization should be used, which opts for the local minimum closest to the target model edf if there are multiple local minima in the GCV/UBRE score.
<code>min.edf</code>	Lower bound on the model edf. Useful for avoiding numerical problems at high smoothing parameter values. Negative for none.

model.matrix.gam    *Extract model matrix from GAM fit*

---

## Description

Obtains the model matrix from a fitted gam object.

## Usage

```
## S3 method for class 'gam':  
model.matrix(object, ...)
```

## Arguments

object            fitted model object of class gam as produced by gam().  
...                other arguments, passed to [predict.gam](#).

## Details

Calls [predict.gam](#) with no newdata argument and type="lpmatrix" in order to obtain the model matrix of object.

## Value

A model matrix.

mono.con

*Monotonicity constraints for a cubic regression spline***Description**

Finds linear constraints sufficient for monotonicity (and optionally upper and/or lower boundedness) of a cubic regression spline. The basis representation assumed is that given by the `gam`, "cr" basis: that is the spline has a set of knots, which have fixed x values, but the y values of which constitute the parameters of the spline.

**Usage**

```
mono.con(x, up=TRUE, lower=NA, upper=NA)
```

**Arguments**

x	The array of knot locations.
up	If TRUE then the constraints imply increase, if FALSE then decrease.
lower	This specifies the lower bound on the spline unless it is NA in which case no lower bound is imposed.
upper	This specifies the upper bound on the spline unless it is NA in which case no upper bound is imposed.

**Details**

Consider the natural cubic spline passing through the points:  $\{x_i, p_i : i = 1 \dots n\}$ . Then it is possible to find a relatively small set of linear constraints on  $\mathbf{p}$  sufficient to ensure monotonicity (and bounds if required):  $\mathbf{A}\mathbf{p} \geq \mathbf{b}$ . Details are given in Wood (1994). This function returns a list containing  $\mathbf{A}$  and  $\mathbf{b}$ .

**Value**

The function returns a list containing constraint matrix  $\mathbf{A}$  and constraint vector  $\mathbf{b}$ .

mroot	<i>Smallest square root of matrix</i>
-------	---------------------------------------

---

**Description**

Find a square root of a positive semi-definite matrix, having as few columns as possible. Uses either pivoted choleski decomposition or singular value decomposition to do this.

**Usage**

```
mroot(A, rank=NULL, method="chol")
```

**Arguments**

A	The positive semi-definite matrix, a square root of which is to be found.
rank	if the rank of the matrix A is known then it should be supplied.
method	"chol" to use pivoted choleski decompositon, which is fast but tends to over-estimate rank. "svd" to use singular value decomposition, which is slow, but is the most accurate way to estimate rank.

**Details**

The routine uses an LAPACK SVD routine, or the LINPACK pivoted Choleski routine. It is primarily of use for turning penalized regression problems into ordinary regression problems.

**Value**

A matrix, **B** with as many columns as the rank of **A**, and such that  $A = BB'$ .

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**Examples**

```
set.seed(0)
a <- matrix(runif(24), 6, 4)
A <- a%*%t(a) ## A is +ve semi-definite, rank 4
B <- mroot(A) ## default pivoted choleski method
tol <- 100*.Machine$double.eps
chol.err <- max(abs(A-B%*%t(B)));chol.err
if (chol.err>tol) warning("mroot (chol) suspect")
B <- mroot(A,method="svd") ## svd method
svd.err <- max(abs(A-B%*%t(B)));svd.err
if (svd.err>tol) warning("mroot (svd) suspect")
```

negbin

*GAM negative binomial family***Description**

The `gam` modelling function is designed to be able to use the `negbin` family (a modification of MASS library `negative.binomial` family by Venables and Ripley), with or without a known  $\theta$  parameter. Two approaches to estimating the `theta` parameter are available:

- If ‘performance iteration’ is used for smoothing parameter estimation (see `gam`), then smoothing parameters are chosen by GCV and `theta` is chosen in order to ensure that the Pearson estimate of the scale parameter is as close as possible to 1, the value that the scale parameter should have.
- If ‘outer iteration’ is used for smoothing parameter selection, and smoothing parameters are chosen by UBRE/AIC (with scale parameter set to 1) then a value of `theta` is searched for which minimizes the AIC of the model. Alternatively If (RE)ML is used for smoothing parameter estimation then a value of `theta` is searched for which maximizes the (restricted) likelihood.

The second option is much slower than the first, but the first can sometimes fail to converge. To use the first option, set the `optimizer` argument of `gam` to "perf".

**Usage**

```
negbin(theta = stop("'theta' must be specified"), link = "log")
```

**Arguments**

<code>theta</code>	Either i) a single value known value of $\theta$ , ii) two values of $\theta$ specifying the endpoints of an interval over which to search for $\theta$ or iii) an array of values of $\theta$ , specifying the set of $\theta$ values to search. (iii) is only available with AIC based $\theta$ estimation.
<code>link</code>	The link function: one of "log", "identity" or "sqrt"

**Details**

If a single value of `theta` is supplied then it is always taken as the known fixed value, and estimation of smoothing parameters is then by UBRE/AIC. If `theta` is two numbers (`theta[2]>theta[1]`) then they are taken as specifying the range of values over which to search for the optimal  $\theta$ . If `theta` is any other array of numbers then they are taken as the discrete set of values of  $\theta$  over which to search for  $\theta$ . The latter option only works with AIC based outer iteration, if performance iteration is used then an array will only be used to define a search range.

If performance iteration is used (see `gam` argument `optimizer`) then the method of estimation is to choose  $\hat{\theta}$  so that the GCV (Pearson) estimate of the scale parameter is one (since the scale parameter is one for the negative binomial). In this case  $\theta$  estimation is nested within the IRLS loop used for GAM fitting. After each call to fit an iteratively weighted additive model to the IRLS pseudodata, the  $\theta$  estimate is updated. This is done by conditioning on all components of the current GCV/Pearson estimator of the scale parameter except  $\theta$  and then searching for the  $\hat{\theta}$  which equates this conditional estimator to one. The search is a simple bisection search after an initial crude line

search to bracket one. The search will terminate at the upper boundary of the search region is a Poisson fit would have yielded an estimated scale parameter  $<1$ .

If outer iteration is used then  $\theta$  is estimated by searching for the value yielding the lowest AIC. The search is either over the supplied array of values, or is a grid search over the supplied range, followed by a golden section search. A full fit is required for each trial  $\theta$ , so the process is slow, but speed is enhanced by making the changes in  $\theta$  as small as possible, from one step to the next, and using the previous smoothing parameter and fitted values to start the new fit.

In a simulation test based on 800 replicates of the first example data, given below, the GCV based (performance iteration) method yielded models with, on average 6% better MSE performance than the AIC based (outer iteration) method. `theta` had a 0.86 correlation coefficient between the two methods. `theta` estimates averaged 3.36 with a standard deviation of 0.44 for the AIC based method and 3.22 with a standard deviation of 0.43 for the GCV based method. However the GCV based method is less computationally reliable, failing in around 4% of replicates.

### Value

An object inheriting from class `family`, with additional elements

<code>dvar</code>	the function giving the first derivative of the variance function w.r.t. <code>mu</code> .
<code>d2var</code>	the function giving the second derivative of the variance function w.r.t. <code>mu</code> .
<code>getTheta</code>	A function for retrieving the value(s) of <code>theta</code> . This also useful for retrieving the estimate of <code>theta</code> after fitting (see example).

### WARNINGS

`gamm` does not support `theta` estimation

The negative binomial functions from the MASS library are no longer supported.

### Author(s)

        data=dat)
plot(b,pages=1)
print(b)
rm(dat)

```

---

new.name

---

*Obtain a name for a new variable that is not already in use*

---

## Description

`gamm` works by transforming a GAMM into something that can be estimated by `lme`, but this involves creating new variables, the names of which should not clash with the names of other variables on which the model depends. This simple service routine checks a suggested name against a list of those in use, and if necessary modifies it so that there is no clash.

## Usage

```
new.name(proposed, old.names)
```

**Arguments**

proposed      a suggested name  
old.names      An array of names that must not be duplicated

**Value**

A name that is not in old.names.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

---

notExp

*Functions for better-than-log positive parameterization*

---

**Description**

It is common practice in statistical optimization to use log-parameterizations when a parameter ought to be positive. i.e. if an optimization parameter  $a$  should be non-negative then we use  $a = \exp(b)$  and optimize with respect to the unconstrained parameter  $b$ . This often works well, but it does imply a rather limited working range for  $b$ : using 8 byte doubles, for example, if  $b$ 's magnitude gets much above 700 then  $a$  overflows or underflows. This can cause problems for numerical optimization methods.

notExp is a monotonic function for mapping the real line into the positive real line with much less extreme underflow and overflow behaviour than `exp`. It is a piece-wise function, but is continuous to second derivative: see the source code for the exact definition, and the example below to see what it looks like.

notLog is the inverse function of notExp.

The major use of these functions was originally to provide more robust `pdMat` classes for `lme` for use by `gamm`. Currently the `notExp2` and `notLog2` functions are used in their place, as a result of changes to the `nlme` optimization routines.

**Usage**

```
notExp(x)
```

```
notLog(x)
```

**Arguments**

`x` Argument array of real numbers (`notExp`) or positive real numbers (`notLog`).

**Value**

An array of function values evaluated at the supplied argument values.

plot(x,notExp(x),type="l")
lines(x,exp(x),col=2)
plot(x,log(notExp(x)),type="l")
lines(x,log(exp(x)),col=2) # redundancy intended
x <- x/4
plot(x,notExp(x),type="l")
lines(x,exp(x),col=2)
plot(x,log(notExp(x)),type="l")
lines(x,log(exp(x)),col=2) # redundancy intended
par(op)
range(notLog(notExp(x))-x) # show that inverse works!
```

---

notExp2

*Alternative to log parameterization for variance components*

---

**Description**

`notLog2` and `notExp2` are alternatives to `log` and `exp` or `notLog` and `notExp` for re-parameterization of variance parameters. They are used by the `pdTens` and `pdIdnot` classes which in turn implement smooths for `gamm`.

The functions are typically used to ensure that smoothing parameters are positive, but the `notExp2` is not monotonic: rather it cycles between ‘effective zero’ and ‘effective infinity’ as its argument changes. The `notLog2` is the inverse function of the `notExp2` only over an interval centered on zero.

Parameterizations using these functions ensure that estimated smoothing parameters remain positive, but also help to ensure that the likelihood is never indefinite: once a working parameter pushes

a smoothing parameter below ‘effective zero’ or above ‘effective infinity’ the cyclic nature of the `notExp2` causes the likelihood to decrease, where otherwise it might simply have flattened.

This parameterization is really just a numerical trick, in order to get `lme` to fit `gamm` models, without failing due to indefiniteness. Note in particular that asymptotic results on the likelihood/REML criterion are not invalidated by the trick, unless parameter estimates end up close to the effective zero or effective infinity: but if this is the case then the asymptotics would also have been invalid for a conventional monotonic parameterization.

This reparameterization was made necessary by some modifications to the underlying optimization method in `lme` introduced in `nlme` 3.1-62. It is possible that future releases will return to the `notExp` parameterization.

Note that you can reset ‘effective zero’ and ‘effective infinity’: see below.

### Usage

```
notExp2(x, d=.Options$mgcv.vc.logrange, b=1/d)
```

```
notLog2(x, d=.Options$mgcv.vc.logrange, b=1/d)
```

### Arguments

<code>x</code>	Argument array of real numbers ( <code>notExp</code> ) or positive real numbers ( <code>notLog</code> ).
<code>d</code>	the range of <code>notExp2</code> runs from $\exp(-d)$ to $\exp(d)$ . To change the range used by <code>gamm</code> reset <code>mgcv.vc.logrange</code> using <code>options</code> .
<code>b</code>	determines the period of the cycle of <code>notExp2</code> .

### Value

An array of function values evaluated at the supplied argument values.

par(op)
```

---

```
null.space.dimension
```

*The basis of the space of un-penalized functions for a TPRS*

---

## Description

The thin plate spline penalties give zero penalty to some functions. The space of these functions is spanned by a set of polynomial terms. `null.space.dimension` finds the dimension of this space,  $M$ , given the number of covariates that the smoother is a function of,  $d$ , and the order of the smoothing penalty,  $m$ . If  $m$  does not satisfy  $2m > d$  then the smallest possible dimension for the null space is found given  $d$  and the requirement that the smooth should be visually smooth.

## Usage

```
null.space.dimension(d, m)
```

## Arguments

`d` is a positive integer - the number of variables of which the t.p.s. is a function.  
`m` a non-negative integer giving the order of the penalty functional, or signalling that the default order should be used.

## Details

Thin plate splines are only visually smooth if the order of the wiggleness penalty,  $m$ , satisfies  $2m > d + 1$ . If  $2m < d + 1$  then this routine finds the smallest  $m$  giving visual smoothness for the given  $d$ , otherwise the supplied  $m$  is used. The null space dimension is given by:

$$M = (m + d - 1)! / (d!(m - 1)!)$$

which is the value returned.

## Value

An integer (array), the null space dimension  $M$ .

## Author(s)

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

null.space.dimension(2,0)
```

pcls

*Penalized Constrained Least Squares Fitting***Description**

Solves least squares problems with quadratic penalties subject to linear equality and inequality constraints using quadratic programming.

**Usage**

```
pcls(M)
```

**Arguments**

- M** is the single list argument to `pcls`. It should have the following elements:
- y** The response data vector.
  - w** A vector of weights for the data (often proportional to the reciprocal of the variance).
  - X** The design matrix for the problem, note that `ncol(M$X)` must give the number of model parameters, while `nrow(M$X)` should give the number of data.
  - C** Matrix containing any linear equality constraints on the problem (e.g.  $\mathbf{C}\mathbf{p} = \mathbf{c}$ ). If you have no equality constraints initialize this to a zero by zero matrix. Note that there is no need to supply the vector  $\mathbf{c}$ , it is defined implicitly by the initial parameter estimates  $\mathbf{p}$ .
  - S** A list of penalty matrices. `S[[i]]` is the smallest contiguous matrix including all the non-zero elements of the  $i$ th penalty matrix. The first parameter it penalizes is given by `off[i]+1` (starting counting at 1).
  - off** Offset values locating the elements of `M$S` in the correct location within each penalty coefficient matrix. (Zero offset implies starting in first location)
  - sp** An array of smoothing parameter estimates.
  - p** An array of feasible initial parameter estimates - these must satisfy the constraints, but should avoid satisfying the inequality constraints as equality constraints.
  - Ain** Matrix for the inequality constraints  $\mathbf{A}_{in}\mathbf{p} > \mathbf{b}_{in}$ .
  - bin** vector in the inequality constraints.

**Details**

This solves the problem:

$$\text{minimise } \|\mathbf{W}^{1/2}(\mathbf{X}\mathbf{p} - \mathbf{y})\|^2 + \sum_{i=1}^m \lambda_i \mathbf{p}' \mathbf{S}_i \mathbf{p}$$

subject to constraints  $\mathbf{C}\mathbf{p} = \mathbf{c}$  and  $\mathbf{A}_{in}\mathbf{p} > \mathbf{b}_{in}$ , w.r.t.  $\mathbf{p}$  given the smoothing parameters  $\lambda_i$ .  $\mathbf{X}$  is a design matrix,  $\mathbf{p}$  a parameter vector,  $\mathbf{y}$  a data vector,  $\mathbf{W}$  a diagonal weight matrix,  $\mathbf{S}_i$  a positive

semi-definite matrix of coefficients defining the  $i$ th penalty and  $\mathbf{C}$  a matrix of coefficients defining the linear equality constraints on the problem. The smoothing parameters are the  $\lambda_i$ . Note that  $\mathbf{X}$  must be of full column rank, at least when projected into the null space of any equality constraints.  $\mathbf{A}_{in}$  is a matrix of coefficients defining the inequality constraints, while  $\mathbf{b}_{in}$  is a vector involved in defining the inequality constraints.

Quadratic programming is used to perform the solution. The method used is designed for maximum stability with least squares problems: i.e.  $\mathbf{X}'\mathbf{X}$  is not formed explicitly. See Gill et al. 1981.

### Value

The function returns an array containing the estimated parameter vector.

---

pdIdnot

*Overflow proof pdMat class for multiples of the identity matrix*

---

## Description

This set of functions is a modification of the `pdMat` class `pdIdent` from library `nlme`. The modification is to replace the log parameterization used in `pdMat` with a `notLog2` parameterization, since the latter avoids indefiniteness in the likelihood and associated convergence problems: the parameters also relate to variances rather than standard deviations, for consistency with the `pdTens` class. The functions are particularly useful for working with Generalized Additive Mixed Models where variance parameters/smoothing parameters can be very large or very small, so that overflow or underflow can be a problem.

These functions would not normally be called directly, although unlike the `pdTens` class it is easy to do so.

## Usage

```

pdIdnot(value = numeric(0), form = NULL,
        nam = NULL, data = sys.frame(sys.parent()))

```

## Arguments

<code>value</code>	Initialization values for parameters. Not normally used.
<code>form</code>	A one sided formula specifying the random effects structure.
<code>nam</code>	a names argument, not normally used with this class.
<code>data</code>	data frame in which to evaluate formula.

**Details**

The following functions are provided: `Dim.pdIndot`, `coef.pdIdnot`, `corMatrix.pdIdnot`, `logDet.pdIdnot`, `pdConstruct.pdIdnot`, `pdFactor.pdIdnot`, `pdMatrix.pdIdnot`, `solve.pdIdnot`, `summary.pdIdnot`. (e.g. `mgcv:::coef.pdIdnot` to access.)

Note that while the `pdFactor` and `pdMatrix` functions return the inverse of the scaled random effect covariance matrix or its factor, the `pdConstruct` function is initialised with estimates of the scaled covariance matrix itself.

**Value**

A class `pdIdnot` object, or related quantities. See the `nlme` documentation for further details.

pdTens

*Functions implementing a pdMat class for tensor product smooths*

---

**Description**

This set of functions implements an `nlme` library `pdMat` class to allow tensor product smooths to be estimated by `lme` as called by `gamm`. Tensor product smooths have a penalty matrix made up of a weighted sum of penalty matrices, where the weights are the smoothing parameters. In the mixed model formulation the penalty matrix is the inverse of the covariance matrix for the random effects of a term, and the smoothing parameters (times a half) are variance parameters to be estimated. It's not possible to transform the problem to make the required random effects covariance matrix look like one of the standard `pdMat` classes: hence the need for the `pdTens` class. A `notLog2` parameterization ensures that the parameters are positive.

These functions (`pdTens`, `pdConstruct.pdTens`, `pdFactor.pdTens`, `pdMatrix.pdTens`, `coef.pdTens` and `summary.pdTens`) would not normally be called directly.

**Usage**

```
pdTens(value = numeric(0), form = NULL,
       nam = NULL, data = sys.frame(sys.parent()))
```

**Arguments**

value	Initialization values for parameters. Not normally used.
form	A one sided formula specifying the random effects structure. The formula should have an attribute <code>S</code> which is a list of the penalty matrices the weighted sum of which gives the inverse of the covariance matrix for these random effects.
nam	a names argument, not normally used with this class.
data	data frame in which to evaluate formula.

**Details**

If using this class directly note that it is worthwhile scaling the `S` matrices to be of ‘moderate size’, for example by dividing each matrix by its largest singular value: this avoids problems with `lme` defaults (`smooth.construct.tensor.smooth.spec` does this automatically).

This appears to be the minimum set of functions required to implement a new `pdMat` class.

Note that while the `pdFactor` and `pdMatrix` functions return the inverse of the scaled random effect covariance matrix or its factor, the `pdConstruct` function is sometimes initialised with estimates of the scaled covariance matrix, and sometimes intialized with its inverse.

**Value**

A class `pdTens` object, or its coefficients or the matrix it represents or the factor of that matrix. `pdFactor` returns the factor as a vector (packed column-wise) (`pdMatrix` always returns a matrix).

---

`place.knots`*Automatically place a set of knots evenly through covariate values*

---

**Description**

Given a univariate array of covariate values, places a set of knots for a regression spline evenly through the covariate values.

**Usage**

```
place.knots(x, nk)
```

**Arguments**

`x`                array of covariate values (need not be sorted).  
`nk`                integer indicating the required number of knots.

**Details**

Places knots evenly throughout a set of covariates. For example, if you had 11 covariate values and wanted 6 knots then a knot would be placed at the first (sorted) covariate value and every second (sorted) value thereafter. With less convenient numbers of data and knots the knots are placed within intervals between data in order to achieve even coverage, where even means having approximately the same number of data between each pair of knots.

**Value**

An array of knot locations.

plot.gam

*Default GAM plotting***Description**

Takes a fitted `gam` object produced by `gam()` and plots the component smooth functions that make it up, on the scale of the linear predictor. Optionally produces term plots for parametric model components as well.

**Usage**

```
## S3 method for class 'gam':
plot(x, residuals=FALSE, rug=TRUE, se=TRUE, pages=0, select=NULL, scale=-1,
      n=100, n2=40, pers=FALSE, theta=30, phi=30, jit=FALSE, xlab=NULL,
      ylab=NULL, main=NULL, ylim=NULL, xlim=NULL, too.far=0.1,
      all.terms=FALSE, shade=FALSE, shade.col="gray80",
      shift=0, trans=I, seWithMean=FALSE, by.resids=FALSE, ...)
```

**Arguments**

<code>x</code>	a fitted <code>gam</code> object as produced by <code>gam()</code> .
<code>residuals</code>	If <code>TRUE</code> then partial residuals are added to plots of 1-D smooths. If <code>FALSE</code> then no residuals are added. If this is an array of the correct length then it is used as the array of residuals to be used for producing partial residuals. If <code>TRUE</code> then the residuals are the working residuals from the IRLS iteration weighted by the IRLS weights. Partial residuals for a smooth term are the residuals that would be obtained by dropping the term concerned from the model, while leaving all other estimates fixed (i.e. the estimates for the term plus the residuals).
<code>rug</code>	when <code>TRUE</code> (default) then the covariate to which the plot applies is displayed as a rug plot at the foot of each plot of a 1-d smooth, and the locations of the covariates are plotted as points on the contour plot representing a 2-d smooth.
<code>se</code>	when <code>TRUE</code> (default) upper and lower lines are added to the 1-d plots at 2 standard errors above and below the estimate of the smooth being plotted while for 2-d plots, surfaces at +1 and -1 standard errors are contoured and overlaid on the contour plot for the estimate. If a positive number is supplied then this number is multiplied by the standard errors when calculating standard error curves or surfaces. See also <code>shade</code> , below.
<code>pages</code>	(default 0) the number of pages over which to spread the output. For example, if <code>pages=1</code> then all terms will be plotted on one page with the layout performed automatically. Set to 0 to have the routine leave all graphics settings as they are.
<code>select</code>	Allows the plot for a single model term to be selected for printing. e.g. if you just want the plot for the second smooth term set <code>select=2</code> .
<code>scale</code>	set to -1 (default) to have the same y-axis scale for each plot, and to 0 for a different y axis for each plot. Ignored if <code>ylim</code> supplied.
<code>n</code>	number of points used for each 1-d plot - for a nice smooth plot this needs to be several times the estimated degrees of freedom for the smooth. Default value 100.
<code>n2</code>	Square root of number of points used to grid estimates of 2-d functions for contouring.

<code>pers</code>	Set to TRUE if you want perspective plots for 2-d terms.
<code>theta</code>	One of the perspective plot angles.
<code>phi</code>	The other perspective plot angle.
<code>jit</code>	Set to TRUE if you want rug plots for 1-d terms to be jittered.
<code>xlab</code>	If supplied then this will be used as the x label for all plots.
<code>ylab</code>	If supplied then this will be used as the y label for all plots.
<code>main</code>	Used as title (or z axis label) for plots if supplied.
<code>ylim</code>	If supplied then this pair of numbers are used as the y limits for each plot.
<code>xlim</code>	If supplied then this pair of numbers are used as the x limits for each plot.
<code>too.far</code>	If greater than 0 then this is used to determine when a location is too far from data to be plotted when plotting 2-D smooths. This is useful since smooths tend to go wild away from data. The data are scaled into the unit square before deciding what to exclude, and <code>too.far</code> is a distance within the unit square.
<code>all.terms</code>	if set to TRUE then the partial effects of parametric model components are also plotted, via a call to <code>termplot</code> . Only terms of order 1 can be plotted in this way.
<code>shade</code>	Set to TRUE to produce shaded regions as confidence bands for smooths (not available for parametric terms, which are plotted using <code>termplot</code> ).
<code>shade.col</code>	define the color used for shading confidence bands.
<code>shift</code>	constant to add to each smooth (on the scale of the linear predictor) before plotting. Can be useful for some diagnostics, or with <code>trans</code> .
<code>trans</code>	function to apply to each smooth (after any shift), before plotting. <code>shift</code> and <code>trans</code> are occasionally useful as a means for getting plots on the response scale, when the model consists only of a single smooth.
<code>seWithMean</code>	if TRUE the component smooths are shown with confidence intervals that include the uncertainty about the overall mean. If FALSE then the uncertainty relates purely to the centred smooth itself. An extension of the argument presented in Nychka (1988) suggests that TRUE results in better coverage performance, and this is also suggested by simulation.
<code>by.resids</code>	Should partial residuals be plotted for terms with <code>by</code> variables? Usually the answer is no, they would be meaningless.
<code>...</code>	other graphics parameters to pass on to plotting commands.

## Details

Produces default plot showing the smooth components of a fitted GAM, and optionally parametric terms as well, when these can be handled by `termplot`.

For plots of 1-d smooths, the x axis of each plot is labelled with the covariate name, while the y axis is labelled `s(cov, edf)` where `cov` is the covariate name, and `edf` the estimated (or user defined for regression splines) degrees of freedom of the smooth.

Contour plots are produced for 2-d smooths with the x-axes labelled with the first covariate name and the y axis with the second covariate name. The main title of the plot is something like `s(var1, var2, edf)`, indicating the variables of which the term is a function, and the estimated degrees of freedom for the term. When `se=TRUE`, estimator variability is shown by overlaying contour plots at plus and minus 1 s.e. relative to the main estimate. If `se` is a positive number then contour plots are at plus or minus `se` multiplied by the s.e. Contour levels are chosen to try and

ensure reasonable separation of the contours of the different plots, but this is not always easy to achieve. Note that these plots can not be modified to the same extent as the other plot.

Smooths of more than 2 variables are not currently dealt with, but simply generate a warning, but see [vis.gam](#).

Fine control of plots for parametric terms can be obtained by calling `termplot` directly, taking care to use its `terms` argument.

Note that, if `seWithMean=TRUE`, the confidence bands include the uncertainty about the overall mean. In other words although each smooth is shown centred, the confidence bands are obtained as if every other term in the model was constrained to have average 0, (average taken over the covariate values), except for the smooth concerned. This seems to correspond more closely to how most users interpret componentwise intervals in practice, and also results in intervals with close to nominal (frequentist) coverage probabilities by an extension of Nychka's (1988) results.

### Value

The function simply generates plots.

### WARNING

Note that the behaviour of this function is not identical to `plot.gam()` in S-PLUS.

Plots of 2-D smooths with standard error contours shown can not easily be customized.

The function can not deal with smooths of more than 2 variables!

### Author(s)

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

Henric Nilsson <[henric.nilsson@statisticon.se](mailto:henric.nilsson@statisticon.se)> donated the code for the `shade` option.

The design is inspired by the S function of the same name described in Chambers and Hastie (1993) (but is not a clone).

---

predict.gam

*Prediction from fitted GAM model*

---

## Description

Takes a fitted `gam` object produced by `gam()` and produces predictions given a new set of values for the model covariates or the original values used for the model fit. Predictions can be accompanied by standard errors, based on the posterior distribution of the model coefficients. The routine can optionally return the matrix by which the model coefficients must be pre-multiplied in order to yield the values of the linear predictor at the supplied covariate values: this is useful for obtaining credible regions for quantities derived from the model (e.g. derivatives of smooths), and for lookup table prediction outside R (see example code below).

**Usage**

```
## S3 method for class 'gam':
predict(object, newdata, type="link", se.fit=FALSE, terms=NULL,
        block.size=1000, newdata.guaranteed=FALSE, na.action=na.pass, ...)
```

**Arguments**

<code>object</code>	a fitted <code>gam</code> object as produced by <code>gam()</code> .
<code>newdata</code>	A data frame or list containing the values of the model covariates at which predictions are required. If this is not provided then predictions corresponding to the original data are returned. If <code>newdata</code> is provided then it should contain all the variables needed for prediction: a warning is generated if not.
<code>type</code>	When this has the value "link" (default) the linear predictor (possibly with associated standard errors) is returned. When <code>type="terms"</code> each component of the linear predictor is returned separately (possibly with standard errors): this includes parametric model components, followed by each smooth component, but excludes any offset and any intercept. <code>type="iterms"</code> is the same, except that any standard errors returned for smooth components will include the uncertainty about the intercept/overall mean. When <code>type="response"</code> predictions on the scale of the response are returned (possibly with approximate standard errors). When <code>type="lpmatrix"</code> then a matrix is returned which yields the values of the linear predictor (minus any offset) when postmultiplied by the parameter vector (in this case <code>se.fit</code> is ignored). The latter option is most useful for getting variance estimates for quantities derived from the model: for example integrated quantities, or derivatives of smooths. A linear predictor matrix can also be used to implement approximate prediction outside R (see example code, below).
<code>se.fit</code>	when this is TRUE (not default) standard error estimates are returned for each prediction.
<code>terms</code>	if <code>type=="terms"</code> then only results for the terms given in this array will be returned.
<code>block.size</code>	maximum number of predictions to process per call to underlying code: larger is quicker, but more memory intensive. Set to < 1 to use total number of predictions as this.
<code>newdata.guaranteed</code>	Set to TRUE to turn off all checking of <code>newdata</code> except for sanity of factor levels: this can speed things up for large prediction tasks, but <code>newdata</code> must be complete, with no NA values for predictors required in the model.
<code>na.action</code>	what to do about NA values in <code>newdata</code> . With the default <code>na.pass</code> , any row of <code>newdata</code> containing NA values for required predictors, gives rise to NA predictions (even if the term concerned has no NA predictors). <code>na.exclude</code> or <code>na.omit</code> result in the dropping of <code>newdata</code> rows, if they contain any NA values for required predictors. If <code>newdata</code> is missing then NA handling is determined from <code>object\$na.action</code> .
<code>...</code>	other arguments.

**Details**

The standard errors produced by `predict.gam` are based on the Bayesian posterior covariance matrix of the parameters  $V_p$  in the fitted `gam` object.

To facilitate plotting with `termplot`, if object possesses an attribute "para.only" and `type=="terms"` then only parametric terms of order 1 are returned (i.e. those that `termplot` can handle).

Note that, in common with other prediction functions, any offset supplied to `gam` as an argument is always ignored when predicting, unlike offsets specified in the gam model formula.

See the examples for how to use the `lpmatrix` for obtaining credible regions for quantities derived from the model.

### Value

If `type=="lpmatrix"` then a matrix is returned which will give a vector of linear predictor values (minus any offset) at the supplied covariate values, when applied to the model coefficient vector. Otherwise, if `se.fit` is TRUE then a 2 item list is returned with items (both arrays) `fit` and `se.fit` containing predictions and associated standard error estimates, otherwise an array of predictions is returned. The dimensions of the returned arrays depends on whether `type` is "terms" or not: if it is then the array is 2 dimensional with each term in the linear predictor separate, otherwise the array is 1 dimensional and contains the linear predictor/predicted values (or corresponding s.e.s). The linear predictor returned termwise will not include the offset or the intercept.

`newdata` can be a data frame, list or model.frame: if it's a model frame then all variables must be supplied.

### WARNING

Note that the behaviour of this function is not identical to `predict.gam()` in `Splus`.

`type=="terms"` does not exactly match what `predict.lm` does for parametric model components.

### Author(s)

Simon N. Wood <simon.wood@r-project.org>

The design is inspired by the `S` function of the same name described in Chambers and Hastie (1993) (but is not a clone).

}

```

## Description

Takes smooth objects produced by `smooth.construct` methods and obtains the matrix mapping the parameters associated with such a smooth to the predicted values of the smooth at a set of new covariate values.

In practice this method is often called via the wrapper function `PredictMat`.

## Usage

```
Predict.matrix(object, data)
Predict.matrix2(object, data)
```

## Arguments

<code>object</code>	is a smooth object produced by a <code>smooth.construct</code> method function. The object contains all the information required to specify the basis for a term of its class, and this information is used by the appropriate <code>Predict.matrix</code> function to produce a prediction matrix for new covariate values. Further details are given in <code>smooth.construct</code> .
<code>data</code>	A data frame containing the values of the (named) covariates at which the smooth term is to be evaluated. Exact requirements are as for <code>smooth.construct</code> and <code>smooth.construct2</code> .

## Details

Smooth terms in a GAM formula are turned into smooth specification objects of class `xx.smooth.spec` during processing of the formula. Each of these objects is converted to a smooth object using an appropriate `smooth.construct` function. The `Predict.matrix` functions are used to obtain the matrix that will map the parameters associated with a smooth term to the predicted values for the term at new covariate values.

Note that new smooth classes can be added by writing a new `smooth.construct` method function and a corresponding `Predict.matrix` method function: see the example code provided for `smooth.construct` for details.

## Value

A matrix which will map the parameters associated with the smooth to the vector of values of the smooth evaluated at the covariate values given in `object`. If the smooth class is one which generates offsets the corresponding offset is returned as attribute `"offset"` of the matrix.

*Predict matrix method functions*

---

**Description**

The various built in smooth classes for use with `gam` have associate `Predict.matrix` method functions to enable prediction from the fitted model.

**Usage**

```
## S3 method for class 'cr.smooth':
Predict.matrix(object, data)
## S3 method for class 'cs.smooth':
Predict.matrix(object, data)
## S3 method for class 'cyclic.smooth':
Predict.matrix(object, data)
## S3 method for class 'pspline.smooth':
Predict.matrix(object, data)
## S3 method for class 'tensor.smooth':
Predict.matrix(object, data)
## S3 method for class 'tprs.smooth':
Predict.matrix(object, data)
## S3 method for class 'ts.smooth':
Predict.matrix(object, data)
```

**Arguments**

object	a smooth object, usually generated by a <code>smooth.construct</code> method having processed a smooth specification object generated by an <code>s</code> or <code>te</code> term in a <code>gam</code> formula.
data	A data frame containing the values of the (named) covariates at which the smooth term is to be evaluated. Exact requirements are as for <code>smooth.construct</code> and <code>smooth.construct2</code> .

**Details**

The `Predict` matrix function is not normally called directly, but is rather used internally by `predict.gam` etc. to predict from a fitted `gam` model. See `Predict.matrix` for more details, or the specific `smooth.construct` pages for details on a particular smooth class.

**Value**

A matrix mapping the coefficients for the smooth term to its values at the supplied data values.

print.gam

*Print a Generalized Additive Model object.*

---

## Description

The default print method for a gam object.

## Usage

```
## S3 method for class 'gam':  
print(x, ...)
```

## Arguments

x, ... fitted model objects of class gam as produced by gam().

## Details

Prints out the family, model formula, effective degrees of freedom for each smooth term, and optimized value of the smoothness selection criterion used. See [gamObject](#) (or `names(x)`) for a listing of what the object contains. [summary.gam](#) provides more detail.

Note that the optimized smoothing parameter selection criterion reported is one of GCV, UBRE(AIC), GACV, negative log marginal likelihood (ML), or negative log restricted likelihood (REML).

## Description

The smooth components of GAMs can be viewed as random effects for estimation purposes. This means that more conventional random effects terms can be incorporated into GAMs in two ways. The first method converts all the smooths into fixed and random components suitable for estimation by standard mixed modelling software. Once the GAM is in this form then conventional random effects are easily added, and the whole model is estimated as a general mixed model. `gamm` and `gamm4` from the `gamm4` package operate in this way.

The second method represents the conventional random effects in a GAM in the same way that the smooths are represented — as penalized regression terms. This method can be used with `gam` by making use of `s(..., "re")` terms in a model: see `smooth.construct.re.smooth.spec`. Alternatively, but less straightforwardly, the `paraPen` argument to `gam` can be used: see `gam.models`. If smoothing parameter estimation is by ML or REML (e.g. `gam(..., method="REML")`) then this approach is a completely conventional likelihood based treatment of random effects.

`gam` can be slow for fitting models with large numbers of random effects, because it does not exploit the sparsity that is often a feature of parametric random effects. It can not be used for models with more coefficients than data. However `gam` is often faster and more reliable than `gamm` or `gamm4`, when the number of random effects is modest.

To facilitate the use of random effects with `gam`, `gam.vcomp` is a utility routine for converting smoothing parameters to variance components. It also provides confidence intervals, if smoothness estimation is by ML or REML.

residuals.gam

*Generalized Additive Model residuals*

---

### Description

Returns residuals for a fitted `gam` model object. Pearson, deviance, working and response residuals are available.

### Usage

```
## S3 method for class 'gam':
residuals(object, type = c("deviance", "pearson", "scaled.pearson",
                           "working", "response"), ...)
```

### Arguments

<code>object</code>	a <code>gam</code> fitted model object.
<code>type</code>	the type of residuals wanted.
<code>...</code>	other arguments.

### Details

Response residuals are the raw residuals (data minus fitted values). Scaled Pearson residuals are raw residuals divided by the standard deviation of the data according to the model mean variance relationship and estimated scale parameter. Pearson residuals are the same, but multiplied by the square root of the scale parameter (so they are independent of the scale parameter):  $((y-\mu)/\sqrt{V(\mu)})$ , where  $y$  is data  $\mu$  is model fitted value and  $V$  is model mean-variance relationship.). Both are provided since not all texts agree on the definition of Pearson residuals. Deviance residuals simply return the deviance residuals defined by the model family. Working residuals are the residuals returned from model fitting at convergence.

There is a special function for `gam` objects because of a bug in the calculation of Pearson residuals in some earlier versions of `residual.glm`.

### Value

An array of residuals.

rig

*Generate inverse Gaussian random deviates***Description**

Generates inverse Gaussian random deviates.

**Usage**

```
rig(n, mean, scale)
```

**Arguments**

n	the number of deviates required. If this has length > 1 then the length is taken as the number of deviates required.
mean	vector of mean values.
scale	vector of scale parameter values (lambda, see below)

**Details**

If  $x$  is the returned vector, then  $E(x) = \text{mean}$  while  $\text{var}(x) = \text{scale} * \text{mean}^3$ . For density and distribution functions see the `statmod` package. The algorithm used is Algorithm 5.7 of Gentle (2003), based on Michael et al. (1976). Note that `scale` here is the scale parameter in the GLM sense, which is the reciprocal of the usual 'lambda' parameter.

**Value**

A vector of inverse Gaussian random deviates.

s

---

*Defining smooths in GAM formulae*

---

**Description**

Function used in definition of smooth terms within `gam` model formulae. The function does not evaluate a (spline) smooth - it exists purely to help set up a model using spline based smooths.

**Usage**

```
s(..., k=-1, fx=FALSE, bs="tp", m=NA, by=NA, xt=NULL, id=NULL, sp=NULL)
```

**Arguments**

- `...` a list of variables that are the covariates that this smooth is a function of.
- `k` the dimension of the basis used to represent the smooth term. The default depends on the number of variables that the smooth is a function of. `k` should not be less than the dimension of the null space of the penalty for the term (see [null.space.dimension](#)), but will be reset if it is. See [choose.k](#) for further information.
- `fx` indicates whether the term is a fixed d.f. regression spline (TRUE) or a penalized regression spline (FALSE).
- `bs` a two letter character string indicating the (penalized) smoothing basis to use. (eg "tp" for thin plate regression spline, "cr" for cubic regression spline). see [smooth.terms](#) for an over view of what is available.
- `m` The order of the penalty for this term (e.g. 2 for normal cubic spline penalty with 2nd derivatives when using default t.p.r.s basis). NA signals autoinitialization. Only some smooth classes use this. The "ps" class can use a 2 item array giving the basis and penalty order separately.
- `by` a numeric or factor variable of the same dimension as each covariate. In the numeric vector case the elements multiply the smooth, evaluated at the corresponding covariate values (a 'varying coefficient model' results). For the numeric `by` variable case the resulting smooth is not usually subject to a centering constraint (so the `by` variable should not be added as an additional main effect). In the factor `by` variable case a replicate of the smooth is produced for each factor level (these smooths will be centered, so the factor usually needs to be added as a main effect as well). See [gam.models](#) for further details. A `by` variable may also be a matrix if covariates are matrices: in this case implements linear functional of a smooth (see [gam.models](#) and [linear.functional.terms](#) for details).
- `xt` Any extra information required to set up a particular basis. Used e.g. to set large data set handling behaviour for "tp" basis.

<code>id</code>	A label or integer identifying this term in order to link its smoothing parameters to others of the same type. If two or more terms have the same <code>id</code> then they will have the same smoothing parameters, and, by default, the same bases (first occurrence defines basis type, but data from all terms used in basis construction). An <code>id</code> with a factor <code>by</code> variable causes the smooths at each factor level to have the same smoothing parameter.
<code>sp</code>	any supplied smoothing parameters for this term. Must be an array of the same length as the number of penalties for this smooth. Positive or zero elements are taken as fixed smoothing parameters. Negative elements signal auto-initialization. Over-rides values supplied in <code>sp</code> argument to <code>gam</code> . Ignored by <code>gamm</code> .

### Details

The function does not evaluate the variable arguments. To use this function to specify use of your own smooths, note the relationships between the inputs and the output object and see the example in `smooth.construct`.

### Value

A class `xx.smooth.spec` object, where `xx` is a basis identifying code given by the `bs` argument of `s`. These `smooth.spec` objects define smooths and are turned into bases and penalties by `smooth.construct` method functions.

The returned object contains the following items:

<code>term</code>	An array of text strings giving the names of the covariates that the term is a function of.
<code>bs.dim</code>	The dimension of the basis used to represent the smooth.
<code>fixed</code>	TRUE if the term is to be treated as a pure regression spline (with fixed degrees of freedom); FALSE if it is to be treated as a penalized regression spline
<code>dim</code>	The dimension of the smoother - i.e. the number of covariates that it is a function of.
<code>p.order</code>	The order of the t.p.r.s. penalty, or 0 for auto-selection of the penalty order.
<code>by</code>	is the name of any <code>by</code> variable as text ("NA" for none).
<code>label</code>	A suitable text label for this smooth term.
<code>xt</code>	The object passed in as argument <code>xt</code> .
<code>id</code>	An identifying label or number for the smooth, linking it to other smooths. Defaults to <code>NULL</code> for no linkage.
<code>sp</code>	array of smoothing parameters for the term (negative for auto-estimation). Defaults to <code>NULL</code> .

---

smooth.construct     *Constructor functions for smooth terms in a GAM*

---

**Description**

Smooth terms in a GAM formula are turned into smooth specification objects of class `xx.smooth.spec` during processing of the formula. Each of these objects is converted to a smooth object using an appropriate `smooth.construct` function. New smooth classes can be added by writing a new `smooth.construct` method function and a corresponding `Predict.matrix` method function (see example code below).

In practice, `smooth.construct` is usually called via `smooth.construct2` and the wrapper function `smoothCon`, in order to handle `by` variables and centering constraints (see the `smoothCon` documentation if you need to handle these things directly, for a user defined smooth class).

**Usage**

```
smooth.construct(object, data, knots)
smooth.construct2(object, data, knots)
```

**Arguments**

`object` is a smooth specification object, generated by an `s` or `te` term in a GAM formula. Objects generated by `s` terms have class `xx.smooth.spec` where `xx` is given by the `bs` argument of `s` (this convention allows the user to add their own smoothers). If `object` is not class `tensor.smooth.spec` it will have the following elements:

**term** The names of the covariates for this smooth, in an array.

**bs.dim** Argument  $k$  of the  $s$  term generating the object. This is the dimension of the basis used to represent the term (or, arguably, 1 greater than the basis dimension for  $cc$  terms).  $bs.dim < 0$  indicates that the constructor should set this to the default value.

**fixed** TRUE if the term is to be unpenalized, otherwise FALSE.

**dim** the number covariates of which this smooth is a function.

**p.order** the order of the smoothness penalty or NA for autoselection of this. This is argument  $m$  of the  $s$  term that generated `object`.

**by** the name of any *by* variable to multiply this term as supplied as an argument to  $s$ . "NA" if there is no such term.

**label** A suitable label for use with this term.

**xt** An object containing information that may be needed for basis setup (used, e.g. by "tp" smooths to pass optional information on big dataset handling).

**id** Any identity associated with this term — used for linking bases and smoothing parameters. NULL by default, indicating no linkage.

**sp** Smoothing parameters for the term. Any negative are estimated, otherwise they are fixed at the supplied value. Unless NULL (default), over-rides `sp` argument to `gam`.

If `object` is of class `tensor.smooth.spec` then it was generated by a `te` term in the GAM formula, and specifies a smooth of several variables with a basis generated as a tensor product of lower dimensional bases. In this case the object will be different and will have the following elements:

**margin** is a list of smooth specification objects of the type listed above, defining the bases which have their tensor product formed in order to construct this term.

**term** is the array of names of the covariates that are arguments of the smooth.

**by** is the name of any *by* variable, or "NA".

**fx** is an array, the elements of which indicate whether (TRUE) any of the margins in the tensor product should be unpenalized.

**label** A suitable label for use with this term.

**dim** is the number of covariates of which this smooth is a function.

**mp** TRUE if multiple penalties are to be used.

**np** TRUE if 1-D marginal smooths are to be re-parameterized in terms of function values.

**id** Any identity associated with this term — used for linking bases and smoothing parameters. NULL by default, indicating no linkage.

**sp** Smoothing parameters for the term. Any negative are estimated, otherwise they are fixed at the supplied value. Unless NULL (default), over-rides `sp` argument to `gam`.

`data` For `smooth.construct` a data frame or list containing the evaluation of the elements of `object$term`, with names given by `object$term`. The last entry will be the *by* variable, if `object$by` is not "NA". For `smooth.construct2` data need only be an object within which `object$term` can be evaluated, the variables can be in any order, and there can be irrelevant variables present as well.

`knots` an optional data frame or list containing the knots relating to `object$term`. If it is NULL then the knot locations are generated automatically. The structure of `knots` should be as for `data`, depending on whether `smooth.construct` or `smooth.construct2` is used.

## Details

There are built in methods for objects with the following classes: `tp.smooth.spec` (thin plate regression splines: see [tprs](#)); `ts.smooth.spec` (thin plate regression splines with shrinkage-to-zero); `cr.smooth.spec` (cubic regression splines: see [cubic.regression.spline](#)); `cs.smooth.spec` (cubic regression splines with shrinkage-to-zero); `cc.smooth.spec` (cyclic cubic regression splines); `ps.smooth.spec` (Eilers and Marx (1986) style P-splines: see [p.spline](#)); `cp.smooth.spec` (cyclic P-splines) `ad.smooth.spec` (adaptive smooths of 1 or 2 variables: see [adaptive.smooth](#)); `tensor.smooth.spec` (tensor product smooths).

There is an implicit assumption that the basis only depends on the knots and/or the set of unique covariate combinations; i.e. that the basis is the same whether generated from the full set of covariates, or just the unique combinations of covariates.

## Value

The input argument `object`, assigned a new class to indicate what type of smooth it is and with at least the following items added:

<code>X</code>	The model matrix from this term. This may have an "offset" attribute: a vector of length <code>nrow(X)</code> containing any contribution of the smooth to the model offset term. <code>by</code> variables do not need to be dealt with here, but if they are then an item <code>by.done</code> must be added to the <code>object</code> .
<code>S</code>	A list of positive semi-definite penalty matrices that apply to this term. The list will be empty if the term is to be left un-penalized.
<code>rank</code>	An array giving the ranks of the penalties.
<code>null.space.dim</code>	The dimension of the penalty null space (before centering).

The following items may be added:

<code>C</code>	The matrix defining any constraints on the term. If this is <code>NULL</code> then <code>smoothCon</code> will add an identifiability constraint that each term should sum to zero over the covariate values. Set to a zero row matrix if no constraints are required. Note that a supplied <code>C</code> is never ignored, even if any <code>by</code> variables of a smooth imply that no constraint is actually needed.
<code>no.rescale</code>	if this is non- <code>NULL</code> then the penalty coefficient matrix of the smooth will not be rescaled for enhanced numerical stability (rescaling is the default, because <a href="#">gamm</a> requires it). Turning off rescaling is useful if the values of the smoothing parameters should be interpretable in a model, for example because they are inverse variance components.
<code>df</code>	the degrees of freedom associated with this term (when unpenalized and unconstrained). If this is <code>null</code> then <code>smoothCon</code> will set it to the basis dimension. <code>smoothCon</code> will reduce this by the number of constraints.
<code>te.ok</code>	<code>FALSE</code> if this term should not be used as a tensor product marginal. Set to <code>TRUE</code> if <code>NULL</code> .
<code>plot.me</code>	Set to <code>FALSE</code> if this smooth should not be plotted by <code>plot.gam</code> . Set to <code>TRUE</code> if <code>NULL</code> .
<code>L</code>	smooths may depend on fewer 'underlying' smoothing parameters than there are elements of <code>S</code> . In this case <code>L</code> is the matrix mapping the vector of underlying log smoothing parameters to the vector of logs of the smoothing parameters actually multiplying the <code>S[[i]]</code> . <code>L=NULL</code> signifies that there is one smoothing parameter per <code>S[[i]]</code> .

Usually the returned object will also include extra information required to define the basis, and used by `Predict.matrix` methods to make predictions using the basis. See the `Details` section for links to the information included for the built in smooth classes.

`tensor.smooth` returned objects will additionally have each element of the `margin` list updated in the same way. `tensor.smooths` also have a list, `XP`, containing re-parameterization matrices for any 1-D marginal terms re-parameterized in terms of function values. This list will have `NULL` entries for marginal smooths that are not re-parameterized, and is only long enough to reach the last re-parameterized marginal in the list.

## WARNING

User defined smooth objects should avoid having attributes names "qrc" or "nCons" as these are used internally to provide constraint free parameterizations.

smooth.construct.ad.smooth.spec  
*Adaptive smooths in GAMs*

---

## Description

`gam` can use adaptive smooths of one or two variables, specified via terms like `s(..., bs="ad", ...)`. (`gam` can not use such terms — check out package `AdaptFit` if this is a problem.) The basis for such a term is a (tensor product of) p-spline(s) or cubic regression spline(s). Discrete P-spline type penalties are applied directly to the coefficients of the basis, but the penalties themselves have a basis representation, allowing the strength of the penalty to vary with the covariates. The coefficients of the penalty basis are the smoothing parameters.

When invoking an adaptive smoother the `k` argument specifies the dimension of the smoothing basis, while the `m` argument specifies the dimension of the penalty basis. For an adaptive smooth of two variables `k` is taken as the dimension of both marginal bases: different marginal basis dimensions can be specified by making `k` a two element vector. Similarly, in the two dimensional case `m` is the dimension of both marginal bases for the penalties, unless it is a two element vector, which specifies different basis dimensions for each marginal (If the penalty basis is based on a thin plate spline then `m` specifies its dimension directly).

By default, P-splines are used for the smoothing and penalty bases, but this can be modified by supplying a list as argument `xt` with a character vector `xt$bs` specifying the smoothing basis type. Only "ps", "cp", "cc" and "cr" may be used for the smoothing basis. The penalty basis is always a B-spline, or a cyclic B-spline for cyclic bases.

The total number of smoothing parameters to be estimated for the term will be the dimension of the penalty basis. Bear in mind that adaptive smoothing places quite severe demands on the data. For example, setting `m=10` for a univariate smooth of 200 data is rather like estimating 10 smoothing parameters, each from a data series of length 20. The problem is particularly serious for smooths of 2 variables, where the number of smoothing parameters required to get reasonable flexibility in the penalty can grow rather fast, but it often requires a very large smoothing basis dimension to make good use of this flexibility. In short, adaptive smooths should be used sparingly and with care.

In practice it is often as effective to simply transform the smoothing covariate as it is to use an adaptive smooth.

## Usage

```
## S3 method for class 'ad.smooth.spec':
smooth.construct(object, data, knots)
```

## Arguments

<code>object</code>	a smooth specification object, usually generated by a term <code>s(..., bs="ad", ...)</code>
<code>data</code>	a list containing just the data (including any <code>by</code> variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The <code>by</code> variable is the last element.
<code>knots</code>	a list containing any knots supplied for basis setup — in same order and with same names as <code>data</code> . Can be <code>NULL</code>

**Details**

The constructor is not normally called directly, but is rather used internally by `gam`. To use for basis setup it is recommended to use `smooth.construct2`.

This class can not be used as a marginal basis in a tensor product smooth, nor by `gamm`.

**Value**

An object of class `"pspline.smooth"` in the 1D case or `"tensor.smooth"` in the 2D case.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**Examples**

```

smooth.construct.cr.smooth.spec
```

*Penalized Cubic regression splines in GAMs*

---

## Description

`gam` can use univariate penalized cubic regression spline smooths, specified via terms like `s(x, bs="cr")`. `s(x, bs="cs")` specifies a penalized cubic regression spline which has had its penalty modified to shrink towards zero at high enough smoothing parameters (as the smoothing parameter goes to infinity a normal cubic spline tends to a straight line.) `s(x, bs="cc")` specifies a cyclic penalized cubic regression spline smooth.

‘Cardinal’ spline bases are used: Wood (2006) sections 4.1.2 and 4.1.3 gives full details. These bases have very low setup costs. For a given basis dimension, `k`, they typically perform a little less well than thin plate regression splines, but a little better than p-splines. See [te](#) to use these bases in tensor product smooths of several variables.

## Usage

```

## S3 method for class 'cr.smooth.spec':
smooth.construct(object, data, knots)
## S3 method for class 'cs.smooth.spec':
smooth.construct(object, data, knots)
## S3 method for class 'cc.smooth.spec':
smooth.construct(object, data, knots)

```

## Arguments

<code>object</code>	a smooth specification object, usually generated by a term <code>s(..., bs="cr", ...)</code> , <code>s(..., bs="cs", ...)</code> or <code>s(..., bs="cc", ...)</code>
<code>data</code>	a list containing just the data (including any <code>by</code> variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The <code>by</code> variable is the last element.
<code>knots</code>	a list containing any knots supplied for basis setup — in same order and with same names as <code>data</code> . Can be <code>NULL</code> . See details.

## Details

The constructor is not normally called directly, but is rather used internally by `gam`. To use for basis setup it is recommended to use `smooth.construct2`.

If they are not supplied then the knots of the spline are placed evenly throughout the covariate values to which the term refers: For example, if fitting 101 data with an 11 knot spline of  $x$  then there would be a knot at every 10th (ordered)  $x$  value. The parameterization used represents the spline in terms of its values at the knots. The values at neighbouring knots are connected by sections of cubic polynomial constrained to be continuous up to and including second derivative at the knots. The resulting curve is a natural cubic spline through the values at the knots (given two extra conditions specifying that the second derivative of the curve should be zero at the two end knots).

The shrinkage version of the smooth, eigen-decomposes the wiggleness penalty matrix, and sets its 2 zero eigenvalues to small multiples of the smallest strictly positive eigenvalue. The penalty is then set to the matrix with eigenvectors corresponding to those of the original penalty, but eigenvalues set to the perturbed versions. This penalty matrix has full rank and shrinks the curve to zero at high enough smoothing parameters.

Note that the cyclic smoother will wrap at the smallest and largest covariate values, unless knots are supplied. If only two knots are supplied then they are taken as the end points of the smoother (provided all the data lie between them), and the remaining knots are generated automatically.

The cyclic smooth is not subject to the condition that second derivatives go to zero at the first and last knots.

## Value

An object of class `"cr.smooth"`, `"cs.smooth"` or `"cyclic.smooth"`. In addition to the usual elements of a smooth class documented under `smooth.construct`, this object will contain:

<code>xp</code>	giving the knot locations used to generate the basis.
<code>BD</code>	class <code>"cyclic.smooth"</code> objects include matrix <code>BD</code> which transforms function values at the knots to second derivatives at the knots.

```

---

smooth.construct.ps.smooth.spec  
*P-splines in GAMs*

---

## Description

`gam` can use univariate P-splines as proposed by Eilers and Marx (1996), specified via terms like `s(x,bs="ps")`. These terms use B-spline bases penalized by discrete penalties applied directly to the basis coefficients. Cyclic P-splines are specified by model terms like `s(x,bs="cp",...)`. These bases can be used in tensor product smooths (see [te](#)).

The advantage of P-splines is the flexible way that penalty and basis order can be mixed. This often provides a useful way of ‘taming’ an otherwise poorly behaved smooth. However, in regular use, splines with derivative based penalties (e.g. "tp" or "cr" bases) tend to result in slightly better MSE performance, presumably because the good approximation theoretic properties of splines are rather closely connected to the use of derivative penalties.

## Usage

```
## S3 method for class 'ps.smooth.spec':
smooth.construct(object, data, knots)
## S3 method for class 'cp.smooth.spec':
smooth.construct(object, data, knots)
```

## Arguments

<code>object</code>	a smooth specification object, usually generated by a term <code>s(x,bs="ps",...)</code> or <code>s(x,bs="cp",...)</code>
<code>data</code>	a list containing just the data (including any <code>by</code> variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The <code>by</code> variable is the last element.
<code>knots</code>	a list containing any knots supplied for basis setup — in same order and with same names as <code>data</code> . Can be <code>NULL</code> . See details for further information.

## Details

A smooth term of the form `s(x,bs="ps",m=c(2,3))` specifies a 2nd order P-spline basis (cubic spline), with a third order difference penalty (0th order is a ridge penalty) on the coefficients. If `m` is a single number then it is taken as the basis order and penalty order. The default is the ‘cubic spline like’ `m=c(2,2)`.

The default basis dimension,  $k$ , is the larger of 10 and  $m[1]+1$  for a "ps" terms and the larger of 10 and  $m[1]$  for a "cp" term.  $m[1]+1$  and  $m[1]$  are the lower limits on basis dimension for the two types.

If knots are supplied, then the number of knots should be one more than the basis dimension (i.e.  $k+1$ ) for a "cp" smooth. For the "ps" basis the number of supplied knots should be  $k + m[1] + 2$ , and the range of the middle  $k-m[1]$  knots should include all the covariate values. See example.

Alternatively, for both types of smooth, 2 knots can be supplied, denoting the lower and upper limits between which the spline can be evaluated (Don't make this range too wide, however, or you can end up with no information about some basis coefficients, because the corresponding basis functions have a span that includes no data!). Note that P-splines don't make much sense with uneven knot spacing.

### Value

An object of class "ps.smooth" or "cp.smooth". See [smooth.construct](#), for the elements that this object will contain.

```
smooth.construct.re.smooth.spec
```

*Simple random effects in GAMs*

---

## Description

`gam` can deal with simple independent random effects, by exploiting the link between smooths and random effects to treat random effects as smooths. `s(x, bs="re")` implements this. Such terms can have any number of predictors, which can be any mixture of numeric or factor variables. The terms produce a parametric interaction of the predictors, and penalize the corresponding coefficients with a multiple of the identity matrix, corresponding to an assumption of i.i.d. normality. See details.

## Usage

```
## S3 method for class 're.smooth.spec':
smooth.construct(object, data, knots)
## S3 method for class 'random.effect':
Predict.matrix(object, data)
```

## Arguments

object	For the <code>smooth.construct</code> method a smooth specification object, usually generated by a term <code>s(x, ..., bs="re", )</code> . For the <code>predict.Matrix</code> method and object of class "random.effect" produced by the <code>smooth.construct</code> method.
data	a list containing just the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The by variable is the last element.
knots	generically a list containing any knots supplied for basis setup — unused at present.

## Details

Exactly how the random effects are implemented is best seen by example. Consider the model term `s(x, z, bs="re")`. This will result in the model matrix component corresponding to  $\sim x:z-1$  being added to the model matrix for the whole model. The coefficients associated with the model matrix component are assumed i.i.d. normal, with unknown variance (to be estimated). This assumption is equivalent to an identity penalty matrix (i.e. a ridge penalty) on the coefficients. Because such a penalty is full rank, random effects terms do not require centering constraints.

If the nature of the random effect specification is not clear, consider a couple more examples: `s(x, bs="re")` results in `model.matrix(~x-1)` being appended to the overall model matrix, while `s(x, v, w, bs="re")` would result in `model.matrix(~x:v:w-1)` being appended to the model matrix. In both cases the corresponding model coefficients are assumed i.i.d. normal, and are hence subject to ridge penalties.

Note that smooth `ids` are not supported for random effect terms, and that `"re"` terms are not suitable for use as marginal smooths in a tensor product smooth.

Random effects implemented in this way do not exploit the sparse structure of many random effects, and may therefore be relatively inefficient for models with large numbers of random effects, when `gamm4` or `gamm` may be better alternatives. Note also that `gam` will not support models with more coefficients than data.

### Value

An object of class `"random.effect"` or a matrix mapping the coefficients of the random effect to the random effects themselves.

### Description

A special `smooth.construct` method function for creating tensor product smooths from any combination of single penalty marginal smooths.

### Usage

```
## S3 method for class 'tensor.smooth.spec':
smooth.construct(object, data, knots)
```

### Arguments

<code>object</code>	a smooth specification object of class <code>tensor.smooth.spec</code> , usually generated by a term like <code>te(x, z)</code> in a <code>gam</code> model formula
<code>data</code>	a list containing just the data (including any <code>by</code> variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The <code>by</code> variable is the last element.
<code>knots</code>	a list containing any knots supplied for basis setup — in same order and with same names as <code>data</code> . Can be <code>NULL</code> . See details for further information.

**Details**

Tensor product smooths are smooths of several variables which allow the degree of smoothing to be different with respect to different variables. They are useful as smooth interaction terms, as they are invariant to linear rescaling of the covariates, which means, for example, that they are insensitive to the measurement units of the different covariates. They are also useful whenever isotropic smoothing is inappropriate. See [te](#), [smooth.construct](#) and [smooth.terms](#).

**Value**

An object of class "tensor.smooth". See [smooth.construct](#), for the elements that this object will contain.

```

---

smooth.construct.tp.smooth.spec

*Penalized thin plate regression splines in GAMs*

---

**Description**

`gam` can use isotropic smooths of any number of variables, specified via terms like `s(x, z, bs="tp", m=3)` (or just `s(x, z)` as this is the default basis). These terms are based on thin plate regression splines. `m` specifies the order of the derivatives in the thin plate spline penalty.

Thin plate regression splines are constructed by starting with the basis and penalty for a full thin plate spline and then truncating this basis in an optimal manner, to obtain a low rank smoother. Details are given in Wood (2003). One key advantage of the approach is that it avoids the knot placement problems of conventional regression spline modelling, but it also has the advantage that smooths of lower rank are nested within smooths of higher rank, so that it is legitimate to use conventional hypothesis testing methods to compare models based on pure regression splines. Note that the basis truncation does not change the meaning of the thin plate spline penalty (it penalizes exactly what it would have penalized for a full thin plate spline).

The t.p.r.s. basis and penalties can become expensive to calculate for large datasets. For this reason the default behaviour is to randomly subsample `max.knots` unique data locations if there are more than `max.knots` such, and to use the sub-sample for basis construction. The sampling is always

done with the same random seed to ensure repeatability (does not reset R RNG). `max.knots` is 3000, by default. Both `seed` and `max.knots` can be modified using the `xt` argument to `s`. Alternatively the user can supply knots from which to construct a basis.

The "ts" smooths are t.p.r.s. with the penalty modified so that the term is shrunk to zero for high enough smoothing parameter, rather than being shrunk towards a function in the penalty null space (see details).

### Usage

```
## S3 method for class 'tp.smooth.spec':
smooth.construct(object, data, knots)
## S3 method for class 'ts.smooth.spec':
smooth.construct(object, data, knots)
```

### Arguments

<code>object</code>	a smooth specification object, usually generated by a term <code>s(...,bs="tp",...)</code> or <code>s(...,bs="ts",...)</code>
<code>data</code>	a list containing just the data (including any <code>by</code> variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The <code>by</code> variable is the last element.
<code>knots</code>	a list containing any knots supplied for basis setup — in same order and with same names as <code>data</code> . Can be <code>NULL</code>

### Details

The default basis dimension for this class is  $k=10 \cdot 3^{(d-1)}$  where  $d$  is the number of covariates for the term. This is essentially arbitrary, and should be checked.

The default is to set  $m$  (the order of derivative in the thin plate spline penalty) to the smallest value satisfying  $2m > d+1$  where  $d$  is the number of covariates of the term: this yields ‘visually smooth’ functions. In any case  $2m > d$  must be satisfied.

The constructor is not normally called directly, but is rather used internally by `gam`. To use for basis setup it is recommended to use `smooth.construct2`.

For these classes the specification `object` will contain information on how to handle large datasets in their `xt` field. The default is to randomly subsample 3000 ‘knots’ from which to produce a tprs basis, if the number of unique predictor variable combinations in excess of 3000. The default can be modified via the `xt` argument to `s`. This is supplied as a list with elements `max.knots` and `seed` containing a number to use in place of 3000, and the random number seed to use (either can be missing).

For these bases `knots` has two uses. Firstly, as mentioned already, for large datasets the calculation of the `tp` basis can be time-consuming. The user can retain most of the advantages of the t.p.r.s. approach by supplying a reduced set of covariate values from which to obtain the basis - typically the number of covariate values used will be substantially smaller than the number of data, and substantially larger than the basis dimension,  $k$ . This approach is the one taken automatically if the number of unique covariate values (combinations) exceeds `max.knots`. The second possibility is to avoid the eigen-decomposition used to find the t.p.r.s. basis altogether and simply use the basis implied by the chosen knots: this will happen if the number of knots supplied matches the basis dimension,  $k$ . For a given basis dimension the second option is faster, but gives poorer results (and the user must be quite careful in choosing knot locations).

The shrinkage version of the smooth, eigen-decomposes the wiggleness penalty matrix, and sets its zero eigenvalues to small multiples of the smallest strictly positive eigenvalue. The penalty is then

set to the matrix with eigenvectors corresponding to those of the original penalty, but eigenvalues set to the perturbed versions. This penalty matrix has full rank and shrinks the curve to zero at high enough smoothing parameters.

### Value

An object of class "tprs.smooth" or "ts.smooth". In addition to the usual elements of a smooth class documented under [smooth.construct](#), this object will contain:

shift	A record of the shift applied to each covariate in order to center it around zero and avoid any co-linearity problems that might otherwise occur in the penalty null space basis of the term.
Xu	A matrix of the unique covariate combinations for this smooth (the basis is constructed by first stripping out duplicate locations).
UZ	The matrix mapping the t.p.r.s. parameters back to the parameters of a full thin plate spline.
null.space.dimension	The dimension of the space of functions that have zero wiggleness according to the wiggleness penalty for this term.

smooth.terms

*Smooth terms in GAM*

---

### Description

Smooth terms are specified in a `gam` formula using `s` and `te` terms. Various smooth classes are available, for different modelling tasks, and users can add smooth classes (see [user.defined.smooth](#)). What defines a smooth class is the basis used to represent the smooth function and quadratic penalty (or multiple penalties) used to penalize the basis coefficients in order to control the degree of smoothness. Smooth classes are invoked directly by `s` terms, or as building blocks for tensor product smoothing via `te` terms (only smooth classes with single penalties can be used in tensor products). The smooths built into the `mgcv` package are all based one way or another on low rank versions of splines. For the full rank versions see Wahba (1990).

Note that smooths can be used rather flexibly in `gam` models. In particular the linear predictor of the GAM can depend on (a discrete approximation to) any linear functional of a smooth term, using `by` variables and the 'summation convention' explained in [linear.functional.terms](#).

The single penalty built in smooth classes are summarized as follows

**Thin plate regression splines** `bs="tp"`. These are low rank isotropic smoothers of any number of covariates. By isotropic is meant that rotation of the covariate co-ordinate system will not change the result of smoothing. By low rank is meant that they have far fewer coefficients than there are data to smooth. They are reduced rank versions of the thin plate splines and use the thin plate spline penalty. They are the default smooth for `s` terms because there is a defined sense in which they are the optimal smoother of any given basis dimension/rank (Wood, 2003). Thin plate regression splines do not have ‘knots’ (at least not in any conventional sense): a truncated eigen-decomposition is used to achieve the rank reduction. See `tpres` for further details.

`bs="ts"` is as `"tp"` but with a small ridge penalty added to the smoothing penalty, so that the whole term can be shrunk to zero.

**Cubic regression splines** `bs="cr"`. These have a cubic spline basis defined by a modest sized set of knots spread evenly through the covariate values. They are penalized by the conventional integrated square second derivative cubic spline penalty. For details see `cubic.regression.spline` and e.g. Wood (2006a).

`bs="cs"` specifies a shrinkage version of `"cr"`.

`bs="cc"` specifies a cyclic cubic regression splines. i.e. a penalized cubic regression splines whose ends match, up to second derivative.

**P-splines** `bs="ps"`. These are P-splines as proposed by Eilers and Marx (1996). They combine a B-spline basis, with a discrete penalty on the basis coefficients, and any sane combination of penalty and basis order is allowed. Although this penalty has no exact interpretation in terms of function shape, in the way that the derivative penalties do, P-splines perform almost as well as conventional splines in many standard applications, and can perform better in particular cases where it is advantageous to mix different orders of basis and penalty.

`bs="cs"` gives a cyclic version of a P-spline.

**Random effects** `bs="re"`. These are parametric terms penalized by a ridge penalty (i.e. the identity matrix). When such a smooth has multiple arguments then it represents the parametric interaction of these arguments, with the coefficients penalized by a ridge penalty. The ridge penalty is equivalent to an assumption that the coefficients are i.i.d. normal random effects. See `smooth.construct.re.smooth.spec`. Note that random effect terms are not suitable for use in tensor product smooths.

Broadly speaking the default penalized thin plate regression splines tend to give the best MSE performance, but they are a little slower to set up than the other bases. The knot based penalized cubic regression splines (with derivative based penalties) usually come next in MSE performance, with the P-splines doing just a little worse. However the P-splines are useful in non-standard situations.

All the preceding classes (and any user defined smooths with single penalties) may be used as marginal bases for tensor product smooths specified via `te` terms, except for `"re"` terms. Tensor product smooths are smooth functions of several variables where the basis is built up from tensor products of bases for smooths of fewer (usually one) variable(s) (marginal bases). The multiple penalties for these smooths are produced automatically from the penalties of the marginal smooths. Wood (2006b) give the general recipe for this construction.

Tensor product smooths often perform better than isotropic smooths when the covariates of a smooth are not naturally on the same scale, so that their relative scaling is arbitrary. For example, if smoothing with respect to time and distance, an isotropic smoother will give very different results if the units are cm and minutes compared to if the units are metres and seconds: a tensor product smooth will give the same answer in both cases (see `te` for an example of this). Note that tensor product terms are knot based, and the thin plate splines seem to offer no advantage over cubic or P-splines as marginal bases.

Finally univariate and bivariate adaptive (`bs="ad"`) smooths are available (see `adaptive.smooth`). These are appropriate when the degree of smoothing should itself

vary with the covariates to be smoothed, and the data contain sufficient information to be able to estimate the appropriate variation. Because this flexibility is achieved by splitting the penalty into several ‘basis penalties’ these terms are not suitable as components of tensor product smooths, and are not supported by `gamm`.

smoothCon

*Prediction/Construction wrapper functions for GAM smooth terms*

---

### Description

Wrapper functions for construction of and prediction from smooth terms in a GAM. The purpose of the wrappers is to allow user-transparent re-parameterization of smooth terms, in order to allow identifiability constraints to be absorbed into the parameterization of each term, if required. The routine also handles ‘by’ variables and construction of identifiability constraints automatically, although this behaviour can be over-ridden.

### Usage

```
smoothCon(object, data, knots, absorb.cons=FALSE,
          scale.penalty=TRUE, n=nrow(data), dataX=NULL,
          null.space.penalty=FALSE, sparse.cons=0)
PredictMat(object, data, n=nrow(data))
```

**Arguments**

<code>object</code>	is a smooth specification object or a smooth object.
<code>data</code>	A data frame, model frame or list containing the values of the (named) covariates at which the smooth term is to be evaluated. If it's a list then <code>n</code> must be supplied.
<code>knots</code>	An optional data frame supplying any knot locations to be supplied for basis construction.
<code>absorb.cons</code>	Set to <code>TRUE</code> in order to have identifiability constraints absorbed into the basis.
<code>scale.penalty</code>	should the penalty coefficient matrix be scaled to have approximately the same 'size' as the inner product of the terms model matrix with itself? This can improve the performance of <code>gamm</code> fitting.
<code>n</code>	number of values for each covariate, or if a covariate is a matrix, the number of rows in that matrix: must be supplied explicitly if <code>data</code> is a list.
<code>dataX</code>	Sometimes the basis should be set up using data in <code>data</code> , but the model matrix should be constructed with another set of data provided in <code>dataX</code> — <code>n</code> is assumed to be the same for both. Facilitates smooth id's.
<code>null.space.penalty</code>	Should an extra penalty be added to the smooth which will penalize the components of the smooth in the penalty null space: provides a way of penalizing terms out of the model altogether.
<code>sparse.cons</code>	If 0 then default sum to zero constraints are used. If 1 then one coefficient is set to zero as constraint for sparse smooths. If 2 then sparse coefficient sum to zero constraints are used for sparse smooths. None of these options has an effect if the smooth supplies its own constraint.

**Details**

These wrapper functions exist to allow smooths specified using `smooth.construct` and `Predict.matrix` method functions to be re-parameterized so that identifiability constraints are no longer required in fitting. This is done in a user transparent manner, but is typically of no importance in use of GAMs. The routine's also handle `by` variables and will create default identifiability constraints.

If a user defined smooth constructor handles `by` variables itself, then its returned smooth object should contain an object `by.done`. If this does not exist then `smoothCon` will use the default code. Similarly if a user defined `Predict.matrix` method handles `by` variables internally then the returned matrix should have a `"by.done"` attribute.

Default centering constraints, that terms should sum to zero over the covariates, are produced unless the smooth constructor includes a matrix `C` of constraints. To have no constraints (in which case you had better have a full rank penalty!) the matrix `C` should have no rows. There is an option to use centering constraint that generate no, or limited infill, if the smoother has a sparse model matrix.

`smoothCon` returns a list of smooths because factor `by` variables result in multiple copies of a smooth, each multiplied by the dummy variable associated with one factor level. `smoothCon` modifies the smooth object labels in the presence of `by` variables, to ensure that they are unique, it also stores the level of a `by` variable factor associated with a smooth, for later use by `PredMat`.

The parameterization used by `gam` can be controlled via `gam.control`.

**Value**

From `smoothCon` a list of `smooth` objects returned by the appropriate `smooth.construct` method function. If constraints are to be absorbed then the objects will have attributes `"qrc"` and `"nCons"`. `"nCons"` is the number of constraints. `"qrc"` is usually the qr decomposition of the constraint matrix (returned by `qr`), but if it is a single positive integer it is the index of the coefficient to set to zero, and if it is a negative number then this indicates that the parameters are to sum to zero.

For `predictMat` a matrix which will map the parameters associated with the smooth to the vector of values of the smooth evaluated at the covariate values given in `object`.

sp.vcov

*Extract smoothing parameter estimator covariance matrix from (RE)ML GAM fit*

---

**Description**

Extracts the estimated covariance matrix for the log smoothing parameter estimates from a (RE)ML estimated `gam` object, provided the fit was with a method that evaluated the required Hessian.

**Usage**

```
sp.vcov(x)
```

**Arguments**

`x` a fitted model object of class `gam` as produced by `gam()`.

**Details**

Just extracts the inverse of the hessian matrix of the negative (restricted) log likelihood w.r.t the log smoothing parameters, if this has been obtained as part of fitting.

**Value**

A matrix corresponding to the estimated covariance matrix of the log smoothing parameter estimators, if this can be extracted, otherwise `NULL`. If the scale parameter has been (RE)ML estimated (i.e. if the method was `"ML"` or `"REML"` and the scale parameter was unknown) then the last row and column relate to the log scale parameter.

step.gam

*Alternatives to step.gam*

---

**Description**

There is no `step.gam` in package `mgcv`. The `mgcv` default for model selection is to use either prediction error criteria such as GCV, GACV, Mallows' Cp/AIC/UBRE or the likelihood based methods of REML or ML. Since the smoothness estimation part of model selection is done in this way it is logically most consistent to perform the rest of model selection in the same way. i.e. to decide which terms to include or omit by looking at changes in GCV, AIC, REML etc.

To facilitate fully automatic model selection the package implements two smooth modification techniques which can be used to allow smooths to be shrunk to zero as part of smoothness selection.

**Shrinkage smoothers** are smoothers in which a small multiple of the identity matrix is added to the smoothing penalty, so that strong enough penalization will shrink all the coefficients of the smooth to zero. Such smoothers can effectively be penalized out of the model altogether, as part of smoothing parameter estimation. 2 classes of these shrinkage smoothers are implemented: "cs" and "ts", based on cubic regression spline and thin plate regression spline smoothers (see [s](#))

**Null space penalization** An alternative is to construct an extra penalty for each smooth which penalizes the space of functions of zero wiggleness according to its existing penalties. If all the smoothing parameters for such a term tend to infinity then the term is penalized to zero, and is effectively dropped from the model. The advantage of this approach is that it can be implemented automatically for any smooth. The `select` argument to [gam](#) causes this latter approach to be used.

REML and ML smoothness selection are equivalent under this approach, and simulation evidence suggests that they tend to perform a little better than prediction error criteria, for model selection.

summary.gam

*Summary for a GAM fit*

---

**Description**

Takes a fitted `gam` object produced by `gam()` and produces various useful summaries from it. (See [sink](#) to divert output to a file.)

**Usage**

```
## S3 method for class 'gam':
summary(object, dispersion=NULL, freq=FALSE, alpha=0, ...)

## S3 method for class 'summary.gam':
print(x, digits = max(3, getOption("digits") - 3),
      signif.stars = getOption("show.signif.stars"), ...)
```

**Arguments**

object	a fitted gam object as produced by gam().
x	a summary.gam object produced by summary.gam().
dispersion	A known dispersion parameter. NULL to use estimate or default (e.g. 1 for Poisson).
freq	By default p-values for individual terms are calculated using the frequentist estimated covariance matrix of the parameter estimators. If this is set to FALSE then the Bayesian covariance matrix of the parameters is used instead. See details.
alpha	adjustment to reference distribution per estimated smoothing parameter.
digits	controls number of digits printed in output.
signif.stars	Should significance stars be printed alongside output.
...	other arguments.

**Details**

Model degrees of freedom are taken as the trace of the influence (or hat) matrix  $\mathbf{A}$  for the model fit. Residual degrees of freedom are taken as number of data minus model degrees of freedom. Let  $\mathbf{P}_i$  be the matrix giving the parameters of the  $i$ th smooth when applied to the data (or pseudodata in the generalized case) and let  $\mathbf{X}$  be the design matrix of the model. Then  $tr(\mathbf{X}\mathbf{P}_i)$  is the edf for the  $i$ th term. Clearly this definition causes the edf's to add up properly!

`print.summary.gam` tries to print various bits of summary information useful for term selection in a pretty way.

If `freq=TRUE` then the frequentist approximation for p-values of smooth terms described in section 4.8.5 of Wood (2006) is used. The approximation is not great. If  $\mathbf{p}_i$  is the parameter vector for the  $i$ th smooth term, and this term has estimated covariance matrix  $\mathbf{V}_i$  then the statistic is  $\mathbf{p}_i' \mathbf{V}_i^{k-} \mathbf{p}_i$ , where  $\mathbf{V}_i^{k-}$  is the rank  $k$  pseudo-inverse of  $\mathbf{V}_i$ , and  $k$  is estimated rank of  $\mathbf{V}_i$ . p-values are obtained as follows. In the case of known dispersion parameter, they are obtained by comparing the chi.sq statistic to the chi-squared distribution with  $k$  degrees of freedom, where  $k$  is the estimated rank of  $\mathbf{V}_i$ . If the dispersion parameter is unknown (in which case it will have been estimated) the statistic is compared to an F distribution with  $k$  upper d.f. and lower d.f. given by the residual degrees of freedom for the model. Typically the p-values will be somewhat too low.

If `freq=FALSE` then 'Bayesian p-values' are returned for the smooth terms, based on a test statistic motivated by Nychka's (1988) analysis of the frequentist properties of Bayesian confidence intervals for smooths. These appear to have better frequentist performance (in terms of power and distribution under the null) than the alternative strictly frequentist approximation. Let  $\mathbf{f}$  denote the vector of values of a smooth term evaluated at the original covariate values and let  $\mathbf{V}_f$  denote the corresponding Bayesian covariance matrix. Let  $\mathbf{V}_f^{r-}$  denote the rank  $r$  pseudoinverse of  $\mathbf{V}_f$ , where  $r$  is the EDF for the term. The statistic used is then

$$T = \mathbf{f}^T \mathbf{V}_f^{r-} \mathbf{f}$$

(this can be calculated efficiently without forming the pseudoinverse explicitly).  $T$  is compared to a chi-squared distribution with degrees of freedom given by the EDF for the term + `alpha *` (number of estimated smoothing parameters), or  $T$  is used as a component in an F ratio statistic if the scale parameter has been estimated. The non-integer rank truncated inverse is constructed to give an approximation varying smoothly between the bounding integer rank approximations, while yielding test statistics with the correct mean and variance.

The definition of Bayesian p-value used is: the probability of observing an  $\mathbf{f}$  less probable than  $\mathbf{0}$ , under the approximation for the posterior for  $\mathbf{f}$  implied by the truncation used in the test statistic.

Note that the p-values distributional approximations start to break down below one effective degree of freedom, and p-values are not reported below 0.5 degrees of freedom.

In simulations the p-values have best behaviour under ML smoothness selection, with REML coming second.

## Value

`summary.gam` produces a list of summary information for a fitted `gam` object.

<code>p.coeff</code>	is an array of estimates of the strictly parametric model coefficients.
<code>p.t</code>	is an array of the <code>p.coeff</code> 's divided by their standard errors.
<code>p.pv</code>	is an array of p-values for the null hypothesis that the corresponding parameter is zero. Calculated with reference to the <code>t</code> distribution with the estimated residual degrees of freedom for the model fit if the dispersion parameter has been estimated, and the standard normal if not.
<code>m</code>	The number of smooth terms in the model.
<code>chi.sq</code>	An array of test statistics for assessing the significance of model smooth terms. See details.
<code>s.pv</code>	An array of approximate p-values for the null hypotheses that each smooth term is zero. Be warned, these are only approximate.
<code>se</code>	array of standard error estimates for all parameter estimates.
<code>r.sq</code>	The adjusted r-squared for the model. Defined as the proportion of variance explained, where original variance and residual variance are both estimated using unbiased estimators. This quantity can be negative if your model is worse than a one parameter constant model, and can be higher for the smaller of two nested models! Note that proportion null deviance explained is probably more appropriate for non-normal errors.
<code>dev.expl</code>	The proportion of the null deviance explained by the model.
<code>edf</code>	array of estimated degrees of freedom for the model terms.
<code>residual.df</code>	estimated residual degrees of freedom.
<code>n</code>	number of data.
<code>method</code>	The smoothing selection criterion used.
<code>sp.criterion</code>	The minimized value of the smoothness selection criterion. Note that for ML and REML methods, what is reported is the negative log marginal likelihood or negative log restricted likelihood.
<code>scale</code>	estimated (or given) scale parameter.
<code>family</code>	the family used.
<code>formula</code>	the original GAM formula.
<code>dispersion</code>	the scale parameter.

<code>pTerms.df</code>	the degrees of freedom associated with each parametric term (excluding the constant).
<code>pTerms.chi.sq</code>	a Wald statistic for testing the null hypothesis that the each parametric term is zero.
<code>pTerms.pv</code>	p-values associated with the tests that each term is zero. For penalized fits these are approximate. The reference distribution is an appropriate chi-squared when the scale parameter is known, and is based on an F when it is not.
<code>cov.unscaled</code>	The estimated covariance matrix of the parameters (or estimators if <code>freq=TRUE</code> ), divided by scale parameter.
<code>cov.scaled</code>	The estimated covariance matrix of the parameters (estimators if <code>freq=TRUE</code> ).
<code>p.table</code>	significance table for parameters
<code>s.table</code>	significance table for smooths
<code>p.Terms</code>	significance table for parametric model terms

**WARNING**

The p-values are approximate: do read the details section.

te

*Define tensor product smooths in GAM formulae***Description**

Function used in definition of tensor product smooth terms within `gam` model formulae. The function does not evaluate a smooth - it exists purely to help set up a model using tensor product based smooths. Designed to construct tensor products from any marginal smooths with a basis-penalty representation (with the restriction that each marginal smooth must have only one penalty).

**Usage**

```
te(..., k=NA,bs="cr",m=NA,d=NA,by=NA,fx=FALSE,
  mp=TRUE,np=TRUE,xt=NULL,id=NULL,sp=NULL)
```

**Arguments**

- `...` a list of variables that are the covariates that this smooth is a function of.
- `k` the dimension(s) of the bases used to represent the smooth term. If not supplied then set to  $5^d$ . If supplied as a single number then this basis dimension is used for each basis. If supplied as an array then the elements are the dimensions of the component (marginal) bases of the tensor product. See [choose.k](#) for further information.
- `bs` array (or single character string) specifying the type for each marginal basis. "cr" for cubic regression spline; "cs" for cubic regression spline with shrinkage; "cc" for periodic/cyclic cubic regression spline; "tp" for thin plate regression spline; "ts" for t.p.r.s. with extra shrinkage. See [smooth.terms](#) for details and full list. User defined bases can also be used here (see [smooth.construct](#) for an example). If only one basis code is given then this is used for all bases.
- `m` The order of the penalty (for smooth classes that use this) for each term. If a single number is given then it is used for all terms. NA autoinitializes. `m` is ignored by some bases (e.g. "cr").
- `d` array of marginal basis dimensions. For example if you want a smooth for 3 covariates made up of a tensor product of a 2 dimensional t.p.r.s. basis and a 1-dimensional basis, then set `d=c(2,1)`. Incompatibilities between built in basis types and dimension will be resolved by resetting the basis type.

<code>by</code>	a numeric or factor variable of the same dimension as each covariate. In the numeric vector case the elements multiply the smooth evaluated at the corresponding covariate values (a ‘varying coefficient model’ results). In the factor case causes a replicate of the smooth to be produced for each factor level. See <a href="#">gam.models</a> for further details. May also be a matrix if covariates are matrices: in this case implements linear functional of a smooth (see <a href="#">gam.models</a> and <a href="#">linear.functional.terms</a> for details).
<code>fx</code>	indicates whether the term is a fixed d.f. regression spline (TRUE) or a penalized regression spline (FALSE).
<code>mp</code>	TRUE to use multiple penalties for the smooth. FALSE to use only a single penalty: single penalties are not recommended - they tend to allow only rather wiggly models.
<code>np</code>	TRUE to use the ‘normal parameterization’ for a tensor product smooth. This represents any 1-d marginal smooths via parameters that are function values at ‘knots’, spread evenly through the data. The parameterization makes the penalties easily interpretable, however it can reduce numerical stability in some cases.
<code>xt</code>	Either a single object, providing any extra information to be passed to each marginal basis constructor, or a list of such objects, one for each marginal basis.
<code>id</code>	A label or integer identifying this term in order to link its smoothing parameters to others of the same type. If two or more smooth terms have the same <code>id</code> then they will have the same smoothing parameters, and, by default, the same bases (first occurrence defines basis type, but data from all terms used in basis construction).
<code>sp</code>	any supplied smoothing parameters for this term. Must be an array of the same length as the number of penalties for this smooth. Positive or zero elements are taken as fixed smoothing parameters. Negative elements signal auto-initialization. Over-rides values supplied in <code>sp</code> argument to <a href="#">gam</a> . Ignored by <a href="#">gamm</a> .

## Details

Smooths of several covariates can be constructed from tensor products of the bases used to represent smooths of one (or sometimes more) of the covariates. To do this ‘marginal’ bases are produced with associated model matrices and penalty matrices, and these are then combined in the manner described in [tensor.prod.model.matrix](#) and [tensor.prod.penalties](#), to produce a single model matrix for the smooth, but multiple penalties (one for each marginal basis). The basis dimension of the whole smooth is the product of the basis dimensions of the marginal smooths.

An option for operating with a single penalty (The Kronecker product of the marginal penalties) is provided, but it is rarely of practical use: the penalty is typically so rank deficient that even the smoothest resulting model will have rather high estimated degrees of freedom.

Tensor product smooths are especially useful for representing functions of covariates measured in different units, although they are typically not quite as nicely behaved as t.p.r.s. smooths for well scaled covariates.

Note also that GAMs constructed from lower rank tensor product smooths are nested within GAMs constructed from higher rank tensor product smooths if the same marginal bases are used in both cases (the marginal smooths themselves are just special cases of tensor product smooths.)

The ‘normal parameterization’ (`np=TRUE`) re-parameterizes the marginal smooths of a tensor product smooth so that the parameters are function values at a set of points spread evenly through the range of values of the covariate of the smooth. This means that the penalty of the tensor product associated with any particular covariate direction can be interpreted as the penalty of the appropriate

marginal smooth applied in that direction and averaged over the smooth. Currently this is only done for marginals of a single variable. This parameterization can reduce numerical stability when used with marginal smooths other than "cc", "cr" and "cs": if this causes problems, set `np=FALSE`.

Note that tensor product smooths should not be centred (have identifiability constraints imposed) if any marginals would not need centering. The constructor for tensor product smooths ensures that this happens.

The function does not evaluate the variable arguments.

## Value

A class `tensor.smooth.spec` object defining a tensor product smooth to be turned into a basis and penalties by the `smooth.construct.tensor.smooth.spec` function.

The returned object contains the following items:

<code>margin</code>	A list of <code>smooth.spec</code> objects of the type returned by <code>s</code> , defining the basis from which the tensor product smooth is constructed.
<code>term</code>	An array of text strings giving the names of the covariates that the term is a function of.
<code>by</code>	is the name of any <code>by</code> variable as text ("NA" for none).
<code>fx</code>	logical array with element for each penalty of the term (tensor product smooths have multiple penalties). TRUE if the penalty is to be ignored, FALSE, otherwise.
<code>label</code>	A suitable text label for this smooth term.
<code>dim</code>	The dimension of the smoother - i.e. the number of covariates that it is a function of.
<code>mp</code>	TRUE is multiple penalties are to be used (default).
<code>np</code>	TRUE to re-parameterize 1-D marginal smooths in terms of function values (default).
<code>id</code>	the <code>id</code> argument supplied to <code>te</code> .
<code>sp</code>	the <code>sp</code> argument supplied to <code>te</code> .

---

tensor.prod.model.matrix

*Utility functions for constructing tensor product smooths*

---

**Description**

Produce model matrices or penalty matrices for a tensor product smooth from the model matrices or penalty matrices for the marginal bases of the smooth.

**Usage**

```
tensor.prod.model.matrix(X)
tensor.prod.penalties(S)
```

**Arguments**

X                    a list of model matrices for the marginal bases of a smooth  
 S                    a list of penalties for the marginal bases of a smooth.

**Details**

If  $X[[1]]$ ,  $X[[2]]$  ...  $X[[m]]$  are the model matrices of the marginal bases of a tensor product smooth then the  $i$ th row of the model matrix for the whole tensor product smooth is given by  $X[[1]][i, ] \%x\% X[[2]][i, ] \%x\% \dots X[[m]][i, ]$ , where  $\%x\%$  is the Kronecker product. Of course the routine operates column-wise, not row-wise!

If  $S[[1]]$ ,  $S[[2]]$  ...  $S[[m]]$  are the penalty matrices for the marginal bases, and  $I[[1]]$ ,  $I[[2]]$  ...  $I[[m]]$  are corresponding identity matrices, each of the same dimension as its corresponding penalty, then the tensor product smooth has  $m$  associate penalties of the form:

$$S[[1]] \%x\% I[[2]] \%x\% \dots I[[m]],$$

$$I[[1]] \%x\% S[[2]] \%x\% \dots I[[m]]$$

...

$$I[[1]] \%x\% I[[2]] \%x\% \dots S[[m]].$$

Of course it's important that the model matrices and penalty matrices are presented in the same order when constructing tensor product smooths.

**Value**

Either a single model matrix for a tensor product smooth, or a list of penalty terms for a tensor product smooth.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

tensor.prod.model.matrix(X)
```

```
S <- list(matrix(c(2, 1, 1, 2), 2, 2), matrix(c(2, 1, 0, 1, 2, 1, 0, 1, 2), 3, 3))
tensor.prod.penalties(S)
```

Tweedie

*GAM Tweedie family***Description**

A Tweedie family, designed for use with `gam` from the `mgcv` library. Restricted to variance function powers between 1 and 2. A useful alternative to `quasi` when a full likelihood is desirable.

**Usage**

```
Tweedie(p=1, link = power(0))
```

**Arguments**

<code>p</code>	the variance of an observation is proportional to its mean to the power <code>p</code> . <code>p</code> must be greater than 1 and less than or equal to 2. 1 would be Poisson, 2 is gamma.
<code>link</code>	The link function: one of "log", "identity", "inverse", "sqrt", or a <a href="#">power</a> link.

**Details**

A Tweedie random variable with  $1 < p < 2$  is a sum of  $N$  gamma random variables where  $N$  has a Poisson distribution. The  $p=1$  case is a generalization of a Poisson distribution and is a discrete distribution supported on integer multiples of the scale parameter. For  $1 < p < 2$  the distribution is supported on the positive reals with a point mass at zero.  $p=2$  is a gamma distribution. As  $p$  gets very close to 1 the continuous distribution begins to converge on the discretely supported limit at  $p=1$ , and is therefore highly multimodal. See [ldTweedie](#) for more on this behaviour.

`Tweedie` is based partly on the [poisson](#) family, and partly on `tweedie` from the `statmod` package. It includes extra components to work with all `mgcv` GAM fitting methods as well as an `aic` function. The required log density evaluation (+ derivatives w.r.t. scale) is based on the series evaluation method of Dunn and Smyth (2005).

Without the restriction on `p` the calculation of Tweedie densities is less straightforward, and there does not currently seem to be an implementation which offers any benefit over `quasi`. If you really need to this case then the `tweedie` package is the place to start.

**Value**

An object inheriting from class `family`, with additional elements

<code>dvar</code>	the function giving the first derivative of the variance function w.r.t. <code>mu</code> .
<code>d2var</code>	the function giving the second derivative of the variance function w.r.t. <code>mu</code> .
<code>ls</code>	A function returning a 3 element array: the saturated log likelihood followed by its first 2 derivatives w.r.t. the scale parameter.

**Author(s)**

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)> modified from Venables and Ripley's `negative.binomial` family.

---

uniquecombs

*find the unique rows in a matrix*

---

## Description

This routine returns a matrix containing all the unique rows of the matrix supplied as its argument. That is, all the duplicate rows are stripped out. Note that the ordering of the rows on exit is not the same as on entry. It also returns an index attribute for relating the result back to the original matrix.

## Usage

```
uniquecombs(x)
```

## Arguments

`x` is an R matrix (numeric)

**Details**

Models with more parameters than unique combinations of covariates are not identifiable. This routine provides a means of evaluating the number of unique combinations of covariates in a model. The routine calls compiled C code.

**Value**

A matrix consisting of the unique rows of  $x$  (in arbitrary order).

The matrix has an "index" attribute. `index[i]` gives the row of the returned matrix that contains row  $i$  of the original matrix.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**See Also**

`unique` can do the same thing, including for non-numeric matrices, but more slowly and without returning the index.

**Examples**

```
X<-matrix(c(1,2,3,1,2,3,4,5,6,1,3,2,4,5,6,1,1,1),6,3,byrow=TRUE)
print(X)
Xu <- uniquecombs(X);Xu
ind <- attr(Xu,"index")
## find the value for row 3 of the original from Xu
Xu[ind[3],];X[3,]
```

---

vcov.gam

---

*Extract parameter (estimator) covariance matrix from GAM fit*

---

**Description**

Extracts the Bayesian posterior covariance matrix of the parameters or frequentist covariance matrix of the parameter estimators from a fitted `gam` object.

**Usage**

```
## S3 method for class 'gam':
vcov(object, freq = FALSE, dispersion = NULL, ...)
```

**Arguments**

<code>object</code>	fitted model object of class <code>gam</code> as produced by <code>gam()</code> .
<code>freq</code>	TRUE to return the frequentist covariance matrix of the parameter estimators, FALSE to return the Bayesian posterior covariance matrix of the parameters.
<code>dispersion</code>	a value for the dispersion parameter: not normally used.
<code>...</code>	other arguments, currently ignored.

**Details**

Basically, just extracts `object$Vc` or `object$Vp` from a `gamObject`.

**Value**

A matrix corresponding to the estimated frequentist covariance matrix of the model parameter estimators/coefficients, or the estimated posterior covariance matrix of the parameters, depending on the argument `freq`.

**Author(s)**

Wood, S.N. (2006) On confidence intervals for generalized additive models based on penalized regression splines. *Australian and New Zealand Journal of Statistics*. 48(4): 445-464.

**See Also**

[gam](#)

**Examples**

```
n <- 100
x <- runif(n)
y <- sin(x*2*pi) + rnorm(n)*.2
mod <- gam(y~s(x,bs="cc",k=10),knots=list(x=seq(0,1,length=10)))
diag(vcov(mod))
```

---

vis.gam

*Visualization of GAM objects*

---

**Description**

Produces perspective or contour plot views of `gam` model predictions, fixing all but the values in `view` to the values supplied in `cond`.

**Usage**

```
vis.gam(x,view=NULL,cond=list(),n.grid=30,too.far=0,col=NA,
        color="heat",contour.col=NULL,se=-1,type="link",
        plot.type="persp",zlim=NULL,nCol=50,...)
```

**Arguments**

`x` a `gam` object, produced by `gam()`

`view` an array containing the names of the two main effect terms to be displayed on the x and y dimensions of the plot. If omitted the first two suitable terms will be used. Note that variables coerced to factors in the model formula won't work as view variables, and `vis.gam` can not detect that this has happened when setting defaults.

<code>cond</code>	a named list of the values to use for the other predictor terms (not in <code>view</code> ). Variables omitted from this list will have the closest observed value to the median for continuous variables, or the most commonly occurring level for factors. Parametric matrix variables have all the entries in each column set to the observed column entry closest to the column median.
<code>n.grid</code>	The number of grid nodes in each direction used for calculating the plotted surface.
<code>too.far</code>	plot grid nodes that are too far from the points defined by the variables given in <code>view</code> can be excluded from the plot. <code>too.far</code> determines what is too far. The grid is scaled into the unit square along with the <code>view</code> variables and then grid nodes more than <code>too.far</code> from the predictor variables are excluded.
<code>col</code>	The colours for the facets of the plot. If this is NA then if <code>se&gt;0</code> the facets are transparent, otherwise the colour scheme specified in <code>color</code> is used. If <code>col</code> is not NA then it is used as the facet colour.
<code>color</code>	the colour scheme to use for plots when <code>se&lt;=0</code> . One of "topo", "heat", "cm", "terrain", "gray" or "bw". Schemes "gray" and "bw" also modify the colors used when <code>se&gt;0</code> .
<code>contour.col</code>	sets the colour of contours when using <code>plot.type="contour"</code> . Default scheme used if NULL.
<code>se</code>	if less than or equal to zero then only the predicted surface is plotted, but if greater than zero, then 3 surfaces are plotted, one at the predicted values minus <code>se</code> standard errors, one at the predicted values and one at the predicted values plus <code>se</code> standard errors.
<code>type</code>	"link" to plot on linear predictor scale and "response" to plot on the response scale.
<code>plot.type</code>	one of "contour" or "persp".
<code>zlim</code>	a two item array giving the lower and upper limits for the z-axis scale. NULL to choose automatically.
<code>nCol</code>	The number of colors to use in color schemes.
<code>...</code>	other options to pass on to <code>persp</code> , <code>image</code> or <code>contour</code> . In particular <code>ticktype="detailed"</code> will add proper axes labelling to the plots.

### Details

The x and y limits are determined by the ranges of the terms named in `view`. If `se<=0` then a single (height colour coded, by default) surface is produced, otherwise three (by default see-through) meshes are produced at mean and +/- `se` standard errors. Parts of the x-y plane too far from data can be excluded by setting `too.far`

All options to the underlying graphics functions can be reset by passing them as extra arguments `...`: such supplied values will always over-ride the default values used by `vis.gam`.

### Value

Simply produces a plot.

### WARNINGS

The routine can not detect that a variable has been coerced to factor within a model formula, and will therefore fail if such a variable is used as a `view` variable. When setting default `view` variables it can not detect this situation either, which can cause failures if the coerced variables are the first, otherwise suitable, variables encountered.

## Chapter 19

# The nlme package

---

ACF

*Autocorrelation Function*

---

### Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `gls` and `lme`.

### Usage

```
ACF(object, maxLag, ...)
```

### Arguments

<code>object</code>	any object from which an autocorrelation function can be obtained. Generally an object resulting from a model fit, from which residuals can be extracted.
<code>maxLag</code>	maximum lag for which the autocorrelation should be calculated.
<code>...</code>	some methods for this generic require additional arguments.

### Value

will depend on the method function used; see the appropriate documentation.

### Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates  
<Bates@stat.wisc.edu>

### References

```

---

ACF.gls

*Autocorrelation Function for gls Residuals*

---

**Description**

This method function calculates the empirical autocorrelation function for the residuals from a `gls` fit. If a grouping variable is specified in `form`, the autocorrelation values are calculated using pairs of residuals within the same group; otherwise all possible residual pairs are used. The autocorrelation function is useful for investigating serial correlation models for equally spaced data.

**Usage**

```
## S3 method for class 'gls':
ACF(object, maxLag, resType, form, na.action, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>gls</code> , representing a generalized least squares fitted model.
<code>maxLag</code>	an optional integer giving the maximum lag for which the autocorrelation should be calculated. Defaults to maximum lag in the residuals.
<code>resType</code>	an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".
<code>form</code>	an optional one sided formula of the form $\sim t$ , or $\sim t   g$ , specifying a time covariate <code>t</code> and, optionally, a grouping factor <code>g</code> . The time covariate must be integer valued. When a grouping factor is present in <code>form</code> , the autocorrelations are calculated using residual pairs within the same group. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups.
<code>na.action</code>	a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>ACF.gls</code> to print an error message and terminate if there are any incomplete observations.
<code>...</code>	some methods for this generic require additional arguments.

**Value**

a data frame with columns `lag` and `ACF` representing, respectively, the lag between residuals within a pair and the corresponding empirical autocorrelation. The returned value inherits from class `ACF`.

```

---

ACF.lme

*Autocorrelation Function for lme Residuals*

---

**Description**

This method function calculates the empirical autocorrelation function for the within-group residuals from an `lme` fit. The autocorrelation values are calculated using pairs of residuals within the innermost group level. The autocorrelation function is useful for investigating serial correlation models for equally spaced data.

**Usage**

```
## S3 method for class 'lme':
ACF(object, maxLag, resType, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>lme</code> , representing a fitted linear mixed-effects model.
<code>maxLag</code>	an optional integer giving the maximum lag for which the autocorrelation should be calculated. Defaults to maximum lag in the within-group residuals.

`resType` an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".

... some methods for this generic require additional arguments – not used.

### Value

a data frame with columns `lag` and `ACF` representing, respectively, the lag between residuals within a pair and the corresponding empirical autocorrelation. The returned value inherits from class `ACF`.

```
fml <- lme(follicles ~ sin(2*pi*Time) + cos(2*pi*Time),
          Ovary, random = ~ sin(2*pi*Time) | Mare)
ACF(fml, maxLag = 11)

# Pinheiro and Bates, p240-241
fmlOver.lme <- lme(follicles ~ sin(2*pi*Time) +
                  cos(2*pi*Time), data=Ovary,
                  random=pdDiag(~sin(2*pi*Time)) )
(ACF.fmlOver <- ACF(fmlOver.lme, maxLag=10))
plot(ACF.fmlOver, alpha=0.01)
```

### Description

The `Alfalfa` data frame has 72 rows and 4 columns.

**Format**

This data frame contains the following columns:

**Variety** a factor with levels `Cossack`, `Ladak`, and `Ranger`

**Date** a factor with levels `None` `S1` `S20` `O7`

**Block** a factor with levels `1` `2` `3` `4` `5` `6`

**Yield** a numeric vector

**Details**

These data are described in Snedecor and Cochran (1980) as an example of a split-plot design. The treatment structure used in the experiment was a  $3 \times 4$  full factorial, with three varieties of alfalfa and four dates of third cutting in 1943. The experimental units were arranged into six blocks, each subdivided into four plots. The varieties of alfalfa (*Cossac*, *Ladak*, and *Ranger*) were assigned randomly to the blocks and the dates of third cutting (*None*, *S1*—September 1, *S20*—September 20, and *O7*—October 7) were randomly assigned to the plots. All four dates were used on each block.

allCoef

*Extract Coefficients from a Set of Objects*

---

**Description**

The extractor function is applied to each object in `...`, with the result being converted to a vector. A `map` attribute is included to indicate which pieces of the returned vector correspond to the original objects in `dots`.

**Usage**

```
allCoef(..., extract)
```

**Arguments**

`...` objects to which `extract` will be applied. Generally these will be model components, such as `corStruct` and `varFunc` objects.

`extract` an optional extractor function. Defaults to `coef`.

**Value**

a vector with all elements, generally coefficients, obtained by applying `extract` to the objects in `...`

**Author(s)**

Jose' Pinheiro and Douglas Bates

anova.gls

*Compare Likelihoods of Fitted Objects*

---

**Description**

When only one fitted model object is present, a data frame with the sums of squares, numerator degrees of freedom, F-values, and P-values for Wald tests for the terms in the model (when `Terms` and `L` are `NULL`), a combination of model terms (when `Terms` is not `NULL`), or linear combinations of the model coefficients (when `L` is not `NULL`). Otherwise, when multiple fitted objects are being compared, a data frame with the degrees of freedom, the (restricted) log-likelihood, the Akaike Information Criterion (AIC), and the Bayesian Information Criterion (BIC) of each object is returned. If `test=TRUE`, whenever two consecutive objects have different number of degrees of freedom, a likelihood ratio statistic, with the associated p-value is included in the returned data frame.

**Usage**

```
## S3 method for class 'gls':
anova(object, ..., test, type, adjustSigma, Terms, L, verbose)
```

**Arguments**

<code>object</code>	a fitted model object inheriting from class <code>gls</code> , representing a generalized least squares fit.
<code>...</code>	other optional fitted model objects inheriting from classes <code>gls</code> , <code>gnls</code> , <code>lm</code> , <code>lme</code> , <code>lmList</code> , <code>nlme</code> , <code>nlsList</code> , or <code>nls</code> .
<code>test</code>	an optional logical value controlling whether likelihood ratio tests should be used to compare the fitted models represented by <code>object</code> and the objects in <code>...</code> . Defaults to <code>TRUE</code> .
<code>type</code>	an optional character string specifying the type of sum of squares to be used in F-tests for the terms in the model. If <code>"sequential"</code> , the sequential sum of squares obtained by including the terms in the order they appear in the model is used; else, if <code>"marginal"</code> , the marginal sum of squares obtained by deleting a term from the model at a time is used. This argument is only used when a single fitted object is passed to the function. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to <code>"sequential"</code> .
<code>adjustSigma</code>	an optional logical value. If <code>TRUE</code> and the estimation method used to obtain <code>object</code> was maximum likelihood, the residual standard error is multiplied by $\sqrt{n_{obs}/(n_{obs} - n_{par})}$ , converting it to a REML-like estimate. This argument is only used when a single fitted object is passed to the function. Default is <code>TRUE</code> .

Terms	an optional integer or character vector specifying which terms in the model should be jointly tested to be zero using a Wald F-test. If given as a character vector, its elements must correspond to term names; else, if given as an integer vector, its elements must correspond to the order in which terms are included in the model. This argument is only used when a single fitted object is passed to the function. Default is <code>NULL</code> .
L	an optional numeric vector or array specifying linear combinations of the coefficients in the model that should be tested to be zero. If given as an array, its rows define the linear combinations to be tested. If names are assigned to the vector elements (array columns), they must correspond to coefficients names and will be used to map the linear combination(s) to the coefficients; else, if no names are available, the vector elements (array columns) are assumed in the same order as the coefficients appear in the model. This argument is only used when a single fitted object is passed to the function. Default is <code>NULL</code> .
verbose	an optional logical value. If <code>TRUE</code> , the calling sequences for each fitted model object are printed with the rest of the output, being omitted if <code>verbose = FALSE</code> . Defaults to <code>FALSE</code> .

**Value**

a data frame inheriting from class `anova.lme`.

**Note**

Likelihood comparisons are not meaningful for objects fit using restricted maximum likelihood and with different fixed effects.

```

```
## S3 method for class 'anova.lme':
print(x, verbose, ...)
```

### Arguments

object	a fitted model object inheriting from class <code>lme</code> , representing a mixed-effects model.
...	other optional fitted model objects inheriting from classes <code>gls</code> , <code>gnls</code> , <code>lm</code> , <code>lme</code> , <code>lmList</code> , <code>nlme</code> , <code>nlsList</code> , or <code>nls</code> .
test	an optional logical value controlling whether likelihood ratio tests should be used to compare the fitted models represented by <code>object</code> and the objects in ... Defaults to <code>TRUE</code> .
type	an optional character string specifying the type of sum of squares to be used in F-tests for the terms in the model. If <code>"sequential"</code> , the sequential sum of squares obtained by including the terms in the order they appear in the model is used; else, if <code>"marginal"</code> , the marginal sum of squares obtained by deleting a term from the model at a time is used. This argument is only used when a single fitted object is passed to the function. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to <code>"sequential"</code> .
adjustSigma	an optional logical value. If <code>TRUE</code> and the estimation method used to obtain <code>object</code> was maximum likelihood, the residual standard error is multiplied by $\sqrt{n_{obs}/(n_{obs} - n_{par})}$ , converting it to a REML-like estimate. This argument is only used when a single fitted object is passed to the function. Default is <code>TRUE</code> .
Terms	an optional integer or character vector specifying which terms in the model should be jointly tested to be zero using a Wald F-test. If given as a character vector, its elements must correspond to term names; else, if given as an integer vector, its elements must correspond to the order in which terms are included in the model. This argument is only used when a single fitted object is passed to the function. Default is <code>NULL</code> .
L	an optional numeric vector or array specifying linear combinations of the coefficients in the model that should be tested to be zero. If given as an array, its rows define the linear combinations to be tested. If names are assigned to the vector elements (array columns), they must correspond to coefficients names and will be used to map the linear combination(s) to the coefficients; else, if no names are available, the vector elements (array columns) are assumed in the same order as the coefficients appear in the model. This argument is only used when a single fitted object is passed to the function. Default is <code>NULL</code> .
x	an object inheriting from class <code>anova.lme</code>
verbose	an optional logical value. If <code>TRUE</code> , the calling sequences for each fitted model object are printed with the rest of the output, being omitted if <code>verbose = FALSE</code> . Defaults to <code>FALSE</code> .

### Value

a data frame inheriting from class `anova.lme`.

### Note

Likelihood comparisons are not meaningful for objects fit using restricted maximum likelihood and with different fixed effects.

---

as.matrix.corStruct

*Matrix of a corStruct Object*

---

## Description

This method function extracts the correlation matrix, or list of correlation matrices, associated with object.

## Usage

```
## S3 method for class 'corStruct':
as.matrix(x, ...)
```

## Arguments

**x** an object inheriting from class `corStruct`, representing a correlation structure.

**...** further arguments passed from other methods.

## Value

If the correlation structure includes a grouping factor, the returned value will be a list with components given by the correlation matrices for each group. Otherwise, the returned value will be a matrix representing the correlation structure associated with `object`.

Assay                                      *Bioassay on Cell Culture Plate*

---

### Description

The Assay data frame has 60 rows and 4 columns.

### Format

This data frame contains the following columns:

**Block** an ordered factor with levels 2 < 1 identifying the block where the wells are measured.

**sample** a factor with levels a to f identifying the sample corresponding to the well.

**dilut** a factor with levels 1 to 5 indicating the dilution applied to the well

**logDens** a numeric vector of the log-optical density

## Details

These data, courtesy of Rich Wolfe and David Lansky from Searle, Inc., come from a bioassay run on a 96-well cell culture plate. The assay is performed using a split-block design. The 8 rows on the plate are labeled A–H from top to bottom and the 12 columns on the plate are labeled 1–12 from left to right. Only the central 60 wells of the plate are used for the bioassay (the intersection of rows B–G and columns 2–11). There are two blocks in the design: Block 1 contains columns 2–6 and Block 2 contains columns 7–11. Within each block, six samples are assigned randomly to rows and five (serial) dilutions are assigned randomly to columns. The response variable is the logarithm of the optical density. The cells are treated with a compound that they metabolize to produce the stain. Only live cells can make the stain, so the optical density is a measure of the number of cells that are alive and healthy.

---

asTable

*Convert groupedData to a matrix*

---

## Description

Create a tabular representation of the response in a balanced groupedData object.

## Usage

```
asTable(object)
```

## Arguments

object            A balanced groupedData object

## Details

A balanced groupedData object can be represented as a matrix or table of response values corresponding to the values of a primary covariate for each level of a grouping factor. This function creates such a matrix representation of the data in object.

## Value

A matrix. The data in the matrix are the values of the response. The columns correspond to the distinct values of the primary covariate and are labelled as such. The rows correspond to the distinct levels of the grouping factor and are labelled as such.

## Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates  
<bates@stat.wisc.edu>

## References

**Examples**

```
asTable(Orthodont)

# Pinheiro and Bates, p. 109
ergoStool.mat <- asTable(ergoStool)
```

---

augPred

*Augmented Predictions*

---

**Description**

Predicted values are obtained at the specified values of `primary`. If `object` has a grouping structure (i.e. `getGroups(object)` is not `NULL`), predicted values are obtained for each group. If `level` has more than one element, predictions are obtained for each level of the `max(level)` grouping factor. If other covariates besides `primary` are used in the prediction model, their average (numeric covariates) or most frequent value (categorical covariates) are used to obtain the predicted values. The original observations are also included in the returned object.

**Usage**

```
augPred(object, primary, minimum, maximum, length.out, ...)
```

**Arguments**

<code>object</code>	a fitted model object from which predictions can be extracted, using a <code>predict</code> method.
<code>primary</code>	an optional one-sided formula specifying the primary covariate to be used to generate the augmented predictions. By default, if a covariate can be extracted from the data used to generate <code>object</code> (using <code>getCovariate</code> ), it will be used as <code>primary</code> .
<code>minimum</code>	an optional lower limit for the primary covariate. Defaults to <code>min(primary)</code> .
<code>maximum</code>	an optional upper limit for the primary covariate. Defaults to <code>max(primary)</code> .
<code>length.out</code>	an optional integer with the number of primary covariate values at which to evaluate the predictions. Defaults to 51.
<code>...</code>	some methods for the generic may require additional arguments.

**Value**

a data frame with four columns representing, respectively, the values of the primary covariate, the groups (if `object` does not have a grouping structure, all elements will be 1), the predicted or observed values, and the type of value in the third column: `original` for the observed values and `predicted` (single or no grouping factor) or `predict.groupVar` (multiple levels of grouping), with `groupVar` replaced by the actual grouping variable name (`fixed` is used for population predictions). The returned object inherits from class `augPred`.

**Note**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `gls`, `lme`, and `lmList`.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**References**

Pinheiro, J. C. and Bates, D. M. (2000), *Mixed-Effects Models in S and S-PLUS*, Springer, New York.

**See Also**

**Examples**

```
fml <- lme(Orthodont, random = ~1)
augPred(fml, length.out = 2, level = c(0,1))
```

---

balancedGrouped      *Create a groupedData object from a matrix*

---

**Description**

Create a `groupedData` object from a data matrix. This function can be used only with balanced data. The opposite conversion, from a `groupedData` object to a `matrix`, is done with `asTable`.

**Usage**

```
balancedGrouped(form, data, labels=NULL, units=NULL)
```

**Arguments**

<code>form</code>	A formula of the form $y \sim x \mid g$ giving the name of the response, the primary covariate, and the grouping factor.
<code>data</code>	A matrix or data frame containing the values of the response grouped according to the levels of the grouping factor (rows) and the distinct levels of the primary covariate (columns). The <code>dimnames</code> of the matrix are used to construct the levels of the grouping factor and the primary covariate.
<code>labels</code>	an optional list of character strings giving labels for the response and the primary covariate. The label for the primary covariate is named <code>x</code> and that for the response is named <code>y</code> . Either label can be omitted.
<code>units</code>	an optional list of character strings giving the units for the response and the primary covariate. The units string for the primary covariate is named <code>x</code> and that for the response is named <code>y</code> . Either units string can be omitted.

**Value**

A balanced groupedData object.

bdf

*Language scores*

---

**Description**

The bdf data frame has 2287 rows and 25 columns of language scores from grade 8 pupils in elementary schools in The Netherlands.

**Usage**

```
data(bdf)
```

**Format**

**schoolNR** a factor denoting the school.

**pupilNR** a factor denoting the pupil.

**IQ.verb** a numeric vector of verbal IQ scores

**IQ.perf** a numeric vector of IQ scores.

**sex** Sex of the student.

**Minority** a factor indicating if the student is a member of a minority group.

**repeatgr** an ordered factor indicating if one or more grades have been repeated.  
**aritPRET** a numeric vector  
**classNR** a numeric vector  
**aritPOST** a numeric vector  
**langPRET** a numeric vector  
**langPOST** a numeric vector  
**ses** a numeric vector of socioeconomic status indicators.  
**denomina** a factor indicating of the school is a public school, a Protestant private school, a Catholic private school, or a non-denominational private school.  
**schoolSES** a numeric vector  
**satiprin** a numeric vector  
**natitest** a factor with levels 0 and 1  
**meetings** a numeric vector  
**currmeet** a numeric vector  
**mixedgra** a factor indicating if the class is a mixed-grade class.  
**percmينو** a numeric vector  
**aritdiff** a numeric vector  
**homework** a numeric vector  
**classsiz** a numeric vector  
**groupsiz** a numeric vector

BIC

*Bayesian Information Criterion*

---

### Description

This generic function calculates the Bayesian information criterion, also known as Schwarz's Bayesian criterion (SBC), for one or several fitted model objects for which a log-likelihood value can be obtained, according to the formula  $-2\log\text{-likelihood} + n_{par} \log(n_{obs})$ , where  $n_{par}$  represents the number of parameters and  $n_{obs}$  the number of observations in the fitted model.

### Usage

```
BIC(object, ...)
```

**Arguments**

`object` a fitted model object, for which there exists a `logLik` method to extract the corresponding log-likelihood, or an object inheriting from class `logLik`.

`...` optional fitted model objects.

**Value**

if just one object is provided, returns a numeric value with the corresponding BIC; if more than one object are provided, returns a `data.frame` with rows corresponding to the objects and columns representing the number of parameters in the model (`df`) and the BIC.

**Author(s)**

**Examples**

```
fm1 <- lm(distance ~ age, data = Orthodont) # no random effects
BIC(fm1)

fm2 <- lme(distance ~ age, data = Orthodont) # random is ~age
BIC(fm1, fm2)
```

---

BIC.logLik

*BIC of a logLik Object*

---

**Description**

This function calculates the Bayesian information criterion, also known as Schwarz's Bayesian criterion (SBC) for an object inheriting from class `logLik`, according to the formula  $-2\log\text{-likelihood} + n_{par} \log(n_{obs})$ , where  $n_{par}$  represents the number of parameters and  $n_{obs}$  the number of observations in the fitted model. When comparing fitted objects, the smaller the BIC, the better the fit.

**Usage**

```
## S3 method for class 'logLik':
BIC(object, ...)
```

**Arguments**

`object` an object inheriting from class `logLik`, usually resulting from applying a `logLik` method to a fitted model object.

`...` some methods for this generic use optional arguments. None are used in this method.

**Value**

a numeric value with the corresponding BIC.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**References**

Schwarz, G. (1978) "Estimating the Dimension of a Model", *Annals of Statistics*, 6, 461-464.

BIC(logLik(fm1))
```

---

BodyWeight

*Rat weight over time for different diets*

---

**Description**

The `BodyWeight` data frame has 176 rows and 4 columns.

**Format**

This data frame contains the following columns:

**weight** a numeric vector giving the body weight of the rat (grams).

**Time** a numeric vector giving the time at which the measurement is made (days).

**Rat** an ordered factor with levels 2 < 3 < 4 < 1 < 8 < 5 < 6 < 7 < 11 < 9 < 10 < 12 < 13 < 15 < 14 < 16 identifying the rat whose weight is measured.

**Diet** a factor with levels 1 to 3 indicating the diet that the rat receives.

**Details**

Hand and Crowder (1996) describe data on the body weights of rats measured over 64 days. These data also appear in Table 2.4 of Crowder and Hand (1990). The body weights of the rats (in grams) are measured on day 1 and every seven days thereafter until day 64, with an extra measurement on day 44. The experiment started several weeks before "day 1." There are three groups of rats, each on a different diet.

---

Cefamandole

*Pharmacokinetics of Cefamandole*

---

**Description**

The Cefamandole data frame has 84 rows and 3 columns.

**Format**

This data frame contains the following columns:

**Subject** a factor giving the subject from which the sample was drawn.

**Time** a numeric vector giving the time at which the sample was drawn (minutes post-injection).

**conc** a numeric vector giving the observed plasma concentration of cefamandole (mcg/ml).

**Details**

Davidian and Giltinan (1995, 1.1, p. 2) describe data obtained during a pilot study to investigate the pharmacokinetics of the drug cefamandole. Plasma concentrations of the drug were measured on six healthy volunteers at 14 time points following an intravenous dose of 15 mg/kg body weight of cefamandole.

Coef *Assign Values to Coefficients*

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all `pdMat`, `corStruct`, and `varFunc` classes, `reStruct`, and `modelStruct`.

**Usage**

```
coef(object, ...) <- value
```

**Arguments**

<code>object</code>	any object representing a fitted model, or, by default, any object with a <code>coef</code> component.
<code>...</code>	some methods for this generic function may require additional arguments.
<code>value</code>	a value to be assigned to the coefficients associated with <code>object</code> .

**Value**

will depend on the method function; see the appropriate documentation.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[coef](#)

**Examples**

```
## see the method function documentation
```

---

`coef.corStruct` *Coefficients of a corStruct Object*

---

**Description**

This method function extracts the coefficients associated with the correlation structure represented by `object`.

**Usage**

```
## S3 method for class 'corStruct':
coef(object, unconstrained, ...)
## S3 method for class 'corStruct':
coef(object, ...) <- value
```

**Arguments**

<code>object</code>	an object inheriting from class <code>corStruct</code> , representing a correlation structure.
<code>unconstrained</code>	a logical value. If <code>TRUE</code> the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If <code>FALSE</code> the coefficients are returned in "natural", possibly constrained, form. Defaults to <code>TRUE</code> .
<code>value</code>	a vector with the replacement values for the coefficients associated with <code>object</code> . It must be a vector with the same length of <code>coef{object}</code> and must be given in unconstrained form.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with the coefficients corresponding to `object`.

**SIDE EFFECTS**

On the left side of an assignment, sets the values of the coefficients of `object` to `value`. `Object` must be initialized (using `Initialize`) before new values can be assigned to its coefficients.

**Author(s)**

Jose Pinheiro and Douglas Bates

**References**

Pinheiro, J. C. and Bates, D. M. (2000), *Mixed-Effects Models in S and S-PLUS*, Springer, New York.

```
cst1 <- corARMA(p = 1, q = 1)
coef(cst1)
```

---

coef.gnls

*Extract gnls Coefficients*

---

**Description**

The estimated coefficients for the nonlinear model represented by `object` are extracted.

**Usage**

```
## S3 method for class 'gnls':
coef(object, ...)
```

**Arguments**

- `object` an object inheriting from class `gnls`, representing a generalized nonlinear least squares fitted model.
- `...` some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with the estimated coefficients for the nonlinear model represented by `object`.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[gnls](#)

**Examples**

```
fm1 <- gnls(weight ~ SSlogis(Time, Asym, xmid, scal), Soybean,
            weights = varPower())
coef(fm1)
```

---

coef.lme

*Extract lme Coefficients*

---

**Description**

The estimated coefficients at level  $i$  are obtained by adding together the fixed effects estimates and the corresponding random effects estimates at grouping levels less or equal to  $i$ . The resulting estimates are returned as a data frame, with rows corresponding to groups and columns to coefficients. Optionally, the returned data frame may be augmented with covariates summarized over groups.

**Usage**

```
## S3 method for class 'lme':
coef(object, augFrame, level, data, which, FUN,
      omitGroupingFactor, subset, ...)
```

**Arguments**

- `object` an object inheriting from class `lme`, representing a fitted linear mixed-effects model.
- `augFrame` an optional logical value. If `TRUE`, the returned data frame is augmented with variables defined in `data`; else, if `FALSE`, only the coefficients are returned. Defaults to `FALSE`.
- `level` an optional positive integer giving the level of grouping to be used in extracting the coefficients from an object with multiple nested grouping levels. Defaults to the highest or innermost level of grouping.

data	an optional data frame with the variables to be used for augmenting the returned data frame when <code>augFrame = TRUE</code> . Defaults to the data frame used to fit object.
which	an optional positive integer or character vector specifying which columns of data should be used in the augmentation of the returned data frame. Defaults to all columns in data.
FUN	an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing data by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables in the frame such as <code>ordered</code> , <code>factor</code> , or <code>numeric</code> . The indicated function will be applied to any group-varying variables of that class. The default functions to be used are <code>mean</code> for numeric factors, and <code>Mode</code> for both <code>factor</code> and <code>ordered</code> . The <code>Mode</code> function, defined internally in <code>gsummary</code> , returns the modal or most popular value of the variable. It is different from the <code>mode</code> function that returns the S-language mode of the variable.
omitGroupingFactor	an optional logical value. When <code>TRUE</code> the grouping factor itself will be omitted from the group-wise summary of data but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to <code>FALSE</code> .
subset	an optional expression specifying a subset
...	some methods for this generic require additional arguments. None are used in this method.

### Value

a data frame inheriting from class `coef.lme` with the estimated coefficients at level `level` and, optionally, other covariates summarized over groups. The returned object also inherits from classes `ranef.lme` and `data.frame`.

### Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

coef(fm1, augFrame = TRUE)
```

---

 coef.lmList                      *Extract lmList Coefficients*

---

### Description

The coefficients of each `lm` object in the `object` list are extracted and organized into a data frame, with rows corresponding to the `lm` components and columns corresponding to the coefficients. Optionally, the returned data frame may be augmented with covariates summarized over the groups associated with the `lm` components.

### Usage

```
## S3 method for class 'lmList':
coef(object, augFrame, data, which, FUN,
      omitGroupingFactor, ...)
```

### Arguments

<code>object</code>	an object inheriting from class <code>lmList</code> , representing a list of <code>lm</code> objects with a common model.
<code>augFrame</code>	an optional logical value. If <code>TRUE</code> , the returned data frame is augmented with variables defined in the data frame used to produce <code>object</code> ; else, if <code>FALSE</code> , only the coefficients are returned. Defaults to <code>FALSE</code> .
<code>data</code>	an optional data frame with the variables to be used for augmenting the returned data frame when <code>augFrame = TRUE</code> . Defaults to the data frame used to fit <code>object</code> .
<code>which</code>	an optional positive integer or character vector specifying which columns of the data frame used to produce <code>object</code> should be used in the augmentation of the returned data frame. Defaults to all variables in the data.
<code>FUN</code>	an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing the data by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If <code>FUN</code> is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If <code>FUN</code> is a list of functions, the names in the list should designate classes of variables in the frame such as <code>ordered</code> , <code>factor</code> , or <code>numeric</code> . The indicated function will be applied to any group-varying variables of that class. The default functions to be used are <code>mean</code> for numeric factors, and <code>Mode</code> for both <code>factor</code> and <code>ordered</code> . The <code>Mode</code> function, defined internally in <code>gsummary</code> , returns the modal or most popular value of the variable. It is different from the <code>mode</code> function that returns the S-language mode of the variable.
<code>omitGroupingFactor</code>	an optional logical value. When <code>TRUE</code> the grouping factor itself will be omitted from the group-wise summary of <code>data</code> but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to <code>FALSE</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a data frame inheriting from class `coef.lmList` with the estimated coefficients for each `lm` component of `object` and, optionally, other covariates summarized over the groups corresponding to the `lm` components. The returned object also inherits from classes `ranef.lmList` and `data.frame`.

coef(fml, augFrame = TRUE)
```

---

`coef.modelStruct`     *Extract modelStruct Object Coefficients*

---

**Description**

This method function extracts the coefficients associated with each component of the `modelStruct` list.

**Usage**

```
## S3 method for class 'modelStruct':
coef(object, unconstrained, ...)
## S3 method for class 'modelStruct':
coef(object, ...) <- value
```

**Arguments**

`object`            an object inheriting from class `modelStruct`, representing a list of model components, such as `corStruct` and `varFunc` objects.

`unconstrained`    a logical value. If `TRUE` the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If `FALSE` the coefficients are returned in "natural", possibly constrained, form. Defaults to `TRUE`.

value a vector with the replacement values for the coefficients associated with object. It must be a vector with the same length of `coef{object}` and must be given in unconstrained form.

... some methods for this generic require additional arguments. None are used in this method.

### Value

a vector with all coefficients corresponding to the components of object.

### SIDE EFFECTS

On the left side of an assignment, sets the values of the coefficients of object to value. Object must be initialized (using `Initialize`) before new values can be assigned to its coefficients.

### Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

---

coef.pdMat

*pdMat Object Coefficients*

---

### Description

This method function extracts the coefficients associated with the positive-definite matrix represented by object.

### Usage

```
## S3 method for class 'pdMat':
coef(object, unconstrained, ...)
## S3 method for class 'pdMat':
coef(object, ...) <- value
```

**Arguments**

`object` an object inheriting from class `pdMat`, representing a positive-definite matrix.

`unconstrained` a logical value. If `TRUE` the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If `FALSE` the upper triangular elements of the positive-definite matrix represented by `object` are returned. Defaults to `TRUE`.

`value` a vector with the replacement values for the coefficients associated with `object`. It must be a vector with the same length of `coef{object}` and must be given in unconstrained form.

`...` some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with the coefficients corresponding to `object`.

**SIDE EFFECTS**

On the left side of an assignment, sets the values of the coefficients of `object` to `value`.

**Usage**

```
## S3 method for class 'reStruct':
coef(object, unconstrained, ...)
## S3 method for class 'reStruct':
coef(object, ...) <- value
```

**Arguments**

<code>object</code>	an object inheriting from class <code>reStruct</code> , representing a random effects structure and consisting of a list of <code>pdMat</code> objects.
<code>unconstrained</code>	a logical value. If <code>TRUE</code> the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If <code>FALSE</code> the coefficients are returned in "natural", possibly constrained, form. Defaults to <code>TRUE</code> .
<code>value</code>	a vector with the replacement values for the coefficients associated with <code>object</code> . It must be a vector with the same length of <code>coef(object)</code> and must be given in unconstrained form.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with the coefficients corresponding to `object`.

**SIDE EFFECTS**

On the left side of an assignment, sets the values of the coefficients of `object` to `value`.

```

---

coef.varFunc

*varFunc Object Coefficients*

---

**Description**

This method function extracts the coefficients associated with the variance function structure represented by `object`.

**Usage**

```
## S3 method for class 'varFunc':
coef(object, unconstrained, allCoef, ...)
## S3 method for class 'varIdent':
coef(object, ...) <- value
```

**Arguments**

<code>object</code>	an object inheriting from class <code>varFunc</code> representing a variance function structure.
<code>unconstrained</code>	a logical value. If <code>TRUE</code> the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If <code>FALSE</code> the coefficients are returned in "natural", generally constrained form. Defaults to <code>TRUE</code> .
<code>allCoef</code>	a logical value. If <code>FALSE</code> only the coefficients which may vary during the optimization are returned. If <code>TRUE</code> all coefficients are returned. Defaults to <code>FALSE</code> .
<code>value</code>	a vector with the replacement values for the coefficients associated with <code>object</code> . It must have the same length of <code>coef{object}</code> and must be given in unconstrained form. <code>Object</code> must be initialized before new values can be assigned to its coefficients.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with the coefficients corresponding to `object`.

**SIDE EFFECTS**

On the left side of an assignment, sets the values of the coefficients of `object` to `value`.

collapse

*Collapse According to Groups*

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Currently, only a `groupedData` method is available.

**Usage**

```
collapse(object, ...)
```

**Arguments**

`object` an object to be collapsed, usually a data frame.  
`...` some methods for the generic may require additional arguments.

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates  
 <bates@stat.wisc.edu>

**See Also**

[collapse.groupedData](#)

**Examples**

```
## see the method function documentation
```

---

```
collapse.groupedData
```

*Collapse a groupedData Object*

---

**Description**

If `object` has a single grouping factor, it is returned unchanged. Else, it is summarized by the values of the `displayLevel` grouping factor (or the combination of its values and the values of the covariate indicated in `preserve`, if any is present). The collapsed data is used to produce a new `groupedData` object, with grouping factor given by the `displayLevel` factor.

**Usage**

```
## S3 method for class 'groupedData':
collapse(object, collapseLevel, displayLevel,
         outer, inner, preserve, FUN, subset, ...)
```

**Arguments**

`object` an object inheriting from class `groupedData`, generally with multiple grouping factors.

`collapseLevel` an optional positive integer or character string indicating the grouping level to use when collapsing the data. Level values increase from outermost to innermost grouping. Default is the highest or innermost level of grouping.

`displayLevel` an optional positive integer or character string indicating the grouping level to use as the grouping factor for the collapsed data. Default is `collapseLevel`.

outer	an optional logical value or one-sided formula, indicating covariates that are outer to the <code>displayLevel</code> grouping factor. If equal to <code>TRUE</code> , the <code>displayLevel</code> element <code>attr(object, "outer")</code> is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to <code>NULL</code> , meaning that no outer covariates are to be used.
inner	an optional logical value or one-sided formula, indicating a covariate that is inner to the <code>displayLevel</code> grouping factor. If equal to <code>TRUE</code> , <code>attr(object, "outer")</code> is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to <code>NULL</code> , meaning that no inner covariate is present.
preserve	an optional one-sided formula indicating a covariate whose levels should be preserved when collapsing the data according to the <code>collapseLevel</code> grouping factor. The collapsing factor is obtained by pasting together the levels of the <code>collapseLevel</code> grouping factor and the values of the covariate to be preserved. Default is <code>NULL</code> , meaning that no covariates need to be preserved.
FUN	an optional summary function or a list of summary functions to be used for collapsing the data. The function or functions are applied only to variables in <code>object</code> that vary within the groups defined by <code>collapseLevel</code> . Invariant variables are always summarized by group using the unique value that they assume within that group. If <code>FUN</code> is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If <code>FUN</code> is a list of functions, the names in the list should designate classes of variables in the data such as <code>ordered</code> , <code>factor</code> , or <code>numeric</code> . The indicated function will be applied to any non-invariant variables of that class. The default functions to be used are <code>mean</code> for numeric factors, and <code>Mode</code> for both <code>factor</code> and <code>ordered</code> . The <code>Mode</code> function, defined internally in <code>gsummary</code> , returns the modal or most popular value of the variable. It is different from the <code>mode</code> function that returns the S-language mode of the variable.
subset	an optional named list. Names can be either positive integers representing grouping levels, or names of grouping factors. Each element in the list is a vector indicating the levels of the corresponding grouping factor to be preserved in the collapsed data. Default is <code>NULL</code> , meaning that all levels are used.
...	some methods for this generic require additional arguments. None are used in this method.

**Value**

a `groupedData` object with a single grouping factor given by the `displayLevel` grouping factor, resulting from collapsing `object` over the levels of the `collapseLevel` grouping factor.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[groupedData](#), [plot.nmGroupedData](#)

## Examples

```
# collapsing by Dog
collapse(Pixel, collapse = 1) # same as collapse(Pixel, collapse = "Dog")
```

---

compareFits	<i>Compare Fitted Objects</i>
-------------	-------------------------------

---

## Description

The columns in `object1` and `object2` are put together in matrices which allow direct comparison of the individual elements for each object. Missing columns in either object are replaced by NAs.

## Usage

```
compareFits(object1, object2, which)
```

## Arguments

`object1, object2`  
data frames, or matrices, with the same row names, but possibly different column names. These will usually correspond to coefficients from fitted objects with a grouping structure (e.g. `lme` and `lmList` objects).

`which`  
an optional integer or character vector indicating which columns in `object1` and `object2` are to be used in the returned object. Defaults to all columns.

## Value

a three-dimensional array, with the third dimension given by the number of unique column names in either `object1` or `object2`. To each column name there corresponds a matrix with as many rows as the rows in `object1` and two columns, corresponding to `object1` and `object2`. The returned object inherits from class `compareFits`.

## Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

## See Also

[plot.compareFits](#), [pairs.compareFits](#), [comparePred](#), [coef](#), [random.effects](#)

## Examples

```
fm1 <- lmList(Orthodont)
fm2 <- lme(fm1)
compareFits(coef(fm1), coef(fm2))
```

---

comparePred	<i>Compare Predictions</i>
-------------	----------------------------

---

**Description**

Predicted values are obtained at the specified values of `primary` for each object. If either `object1` or `object2` have a grouping structure (i.e. `getGroups(object)` is not `NULL`), predicted values are obtained for each group. When both objects determine groups, the group levels must be the same. If other covariates besides `primary` are used in the prediction model, their group-wise averages (numeric covariates) or most frequent values (categorical covariates) are used to obtain the predicted values. The original observations are also included in the returned object.

**Usage**

```
comparePred(object1, object2, primary, minimum, maximum,
            length.out, level, ...)
```

**Arguments**

<code>object1, object2</code>	fitted model objects, from which predictions can be extracted using the <code>predict</code> method.
<code>primary</code>	an optional one-sided formula specifying the primary covariate to be used to generate the augmented predictions. By default, if a covariate can be extracted from the data used to generate the objects (using <code>getCovariate</code> ), it will be used as <code>primary</code> .
<code>minimum</code>	an optional lower limit for the primary covariate. Defaults to <code>min(primary)</code> , after <code>primary</code> is evaluated in the data used in fitting <code>object1</code> .
<code>maximum</code>	an optional upper limit for the primary covariate. Defaults to <code>max(primary)</code> , after <code>primary</code> is evaluated in the data used in fitting <code>object1</code> .
<code>length.out</code>	an optional integer with the number of primary covariate values at which to evaluate the predictions. Defaults to 51.
<code>level</code>	an optional integer specifying the desired prediction level. Levels increase from outermost to innermost grouping, with level 0 representing the population (fixed effects) predictions. Only one level can be specified. Defaults to the innermost level.
<code>...</code>	some methods for the generic may require additional arguments.

**Value**

a data frame with four columns representing, respectively, the values of the primary covariate, the groups (if `object` does not have a grouping structure, all elements will be 1), the predicted or observed values, and the type of value in the third column: the objects' names are used to classify the predicted values and `original` is used for the observed values. The returned object inherits from classes `comparePred` and `augPred`.

**Note**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `gls`, `lme`, and `lmList`.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates  
<bates@stat.wisc.edu>

**See Also**

**Examples**

```
fm1 <- lme(distance ~ age * Sex, data = Orthodont, random = ~ age)
fm2 <- update(fm1, distance ~ age)
comparePred(fm1, fm2, length.out = 2)
```

---

corAR1

*AR(1) Correlation Structure*

---

**Description**

This function is a constructor for the `corAR1` class, representing an autocorrelation structure of order 1. Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

**Usage**

```
corAR1(value, form, fixed)
```

**Arguments**

<code>value</code>	the value of the lag 1 autocorrelation, which must be between -1 and 1. Defaults to 0 (no autocorrelation).
<code>form</code>	a one sided formula of the form $\sim t$ , or $\sim t \mid g$ , specifying a time covariate $t$ and, optionally, a grouping factor $g$ . A covariate for this correlation structure must be integer valued. When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups.
<code>fixed</code>	an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.

**Value**

an object of class `corAR1`, representing an autocorrelation structure of order 1.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates  
<bates@stat.wisc.edu>

corARMA

*ARMA(p,q) Correlation Structure***Description**

This function is a constructor for the `corARMA` class, representing an autocorrelation-moving average correlation structure of order  $(p, q)$ . Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

**Usage**

```
corARMA(value, form, p, q, fixed)
```

**Arguments**

<code>value</code>	a vector with the values of the autoregressive and moving average parameters, which must have length $p + q$ and all elements between -1 and 1. Defaults to a vector of zeros, corresponding to uncorrelated observations.
<code>form</code>	a one sided formula of the form $\sim t$ , or $\sim t   g$ , specifying a time covariate $t$ and, optionally, a grouping factor $g$ . A covariate for this correlation structure must be integer valued. When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups.
<code>p, q</code>	non-negative integers specifying respectively the autoregressive order and the moving average order of the ARMA structure. Both default to 0.
<code>fixed</code>	an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.

**Value**

an object of class `corARMA`, representing an autocorrelation-moving average correlation structure.

corCAR1

*Continuous AR(1) Correlation Structure***Description**

This function is a constructor for the `corCAR1` class, representing an autocorrelation structure of order 1, with a continuous time covariate. Objects created using this constructor must be later initialized using the appropriate `Initialize` method.

**Usage**

```
corCAR1(value, form, fixed)
```

**Arguments**

value	the correlation between two observations one unit of time apart. Must be between 0 and 1. Defaults to 0.2.
form	a one sided formula of the form $\sim t$ , or $\sim t   g$ , specifying a time covariate $t$ and, optionally, a grouping factor $g$ . Covariates for this correlation structure need not be integer valued. When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups.

`fixed` an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to `FALSE`, in which case the coefficients are allowed to vary.

### Value

an object of class `corCAR1`, representing an autocorrelation structure of order 1, with a continuous time covariate.

```

---

corClasses

*Correlation Structure Classes*

---

### Description

Standard classes of correlation structures (`corStruct`) available in the `nlme` library.

**Value**

Available standard classes:

<code>corAR1</code>	autoregressive process of order 1.
<code>corARMA</code>	autoregressive moving average process, with arbitrary orders for the autoregressive and moving average components.
<code>corCAR1</code>	continuous autoregressive process (AR(1) process for a continuous time covariate).
<code>corCompSymm</code>	compound symmetry structure corresponding to a constant correlation.
<code>corExp</code>	exponential spatial correlation.
<code>corGaus</code>	Gaussian spatial correlation.
<code>corLin</code>	linear spatial correlation.
<code>corRatio</code>	Rational quadratics spatial correlation.
<code>corSpher</code>	spherical spatial correlation.
<code>corSymm</code>	general correlation matrix, with no additional structure.

**Note**

Users may define their own `corStruct` classes by specifying a constructor function and, at a minimum, methods for the functions `corMatrix` and `coef`. For examples of these functions, see the methods for classes `corSymm` and `corAR1`.

`corCompSymm`

*Compound Symmetry Correlation Structure*

---

**Description**

This function is a constructor for the `corCompSymm` class, representing a compound symmetry structure corresponding to uniform correlation. Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

**Usage**

```
corCompSymm(value, form, fixed)
```

**Arguments**

value	the correlation between any two correlated observations. Defaults to 0.
form	a one sided formula of the form $\sim t$ , or $\sim t \mid g$ , specifying a time covariate $t$ and, optionally, a grouping factor $g$ . When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups.
fixed	an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.

**Value**

an object of class `corCompSymm`, representing a compound symmetry correlation structure.

**See Also**

[corClasses](#), [Initialize.corStruct](#), [summary.corStruct](#)

**Examples**

```
## covariate is observation order and grouping factor is Subject
cs1 <- corCompSymm(0.5, form = ~ 1 | Subject)

# Pinheiro and Bates, pp. 222-225
fm1BW.lme <- lme(weight ~ Time * Diet, BodyWeight,
               random = ~ Time)

# p. 223
fm2BW.lme <- update(fm1BW.lme, weights = varPower())

# p. 225
cs1CompSymm <- corCompSymm(value = 0.3, form = ~ 1 | Subject)
cs2CompSymm <- corCompSymm(value = 0.3, form = ~ age | Subject)
cs1CompSymm <- Initialize(cs1CompSymm, data = Orthodont)
corMatrix(cs1CompSymm)
```

corExp

*Exponential Correlation Structure***Description**

This function is a constructor for the `corExp` class, representing an exponential spatial correlation structure. Letting  $d$  denote the range and  $n$  denote the nugget effect, the correlation between two observations a distance  $r$  apart is  $\exp(-r/d)$  when no nugget effect is present and  $(1 - n) \exp(-r/d)$  when a nugget effect is assumed. Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

**Usage**

```
corExp(value, form, nugget, metric, fixed)
```

**Arguments**

value	an optional vector with the parameter values in constrained form. If <code>nugget</code> is <code>FALSE</code> , <code>value</code> can have only one element, corresponding to the "range" of the exponential correlation structure, which must be greater than zero. If <code>nugget</code> is <code>TRUE</code> , meaning that a nugget effect is present, <code>value</code> can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to <code>numeric(0)</code> , which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when <code>object</code> is initialized.
form	a one sided formula of the form $\sim S_1 + \dots + S_p$ , or $\sim S_1 + \dots + S_p \mid g$ , specifying spatial covariates $S_1$ through $S_p$ and, optionally, a grouping factor $g$ . When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups.
nugget	an optional logical value indicating whether a nugget effect is present. Defaults to <code>FALSE</code> .
metric	an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".
fixed	an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.

**Value**

an object of class `corExp`, also inheriting from class `corSpatial`, representing an exponential spatial correlation structure.

anova(fm3BW.lme, fm4BW.lme)

```

---

 corFactor

*Factor of a Correlation Matrix*

---

### Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all `corStruct` classes.

### Usage

```
corFactor(object, ...)
```

### Arguments

`object` an object from which a correlation matrix can be extracted.  
`...` some methods for this generic function require additional arguments.

### Value

will depend on the method function used; see the appropriate documentation.

### Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates  
 <bates@stat.wisc.edu>

### See Also

[corFactor.corStruct](#), [recalc.corStruct](#)

### Examples

```
## see the method function documentation
```

---

 corFactor.corStruct

*Factor of a corStruct Object Matrix*

---

### Description

This method function extracts a transpose inverse square-root factor, or a series of transpose inverse square-root factors, of the correlation matrix, or list of correlation matrices, represented by `object`. Letting  $\Sigma$  denote a correlation matrix, a square-root factor of  $\Sigma$  is any square matrix  $L$  such that  $\Sigma = L'L$ . This method extracts  $L^{-t}$ .

### Usage

```
## S3 method for class 'corStruct':
corFactor(object, ...)
```

**Arguments**

`object` an object inheriting from class `corStruct` representing a correlation structure, which must have been initialized (using `Initialize`).

`...` some methods for this generic require additional arguments. None are used in this method.

**Value**

If the correlation structure does not include a grouping factor, the returned value will be a vector with a transpose inverse square-root factor of the correlation matrix associated with `object` stacked column-wise. If the correlation structure includes a grouping factor, the returned value will be a vector with transpose inverse square-root factors of the correlation matrices for each group, stacked by group and stacked column-wise within each group.

**Note**

This method function is used intensively in optimization algorithms and its value is returned as a vector for efficiency reasons. The `corMatrix` method function can be used to obtain transpose inverse square-root factors in matrix form.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

**Examples**

```
cs1 <- corAR1(form = ~1 | Subject)
cs1 <- Initialize(cs1, data = Orthodont)
corFactor(cs1)
```

---

corGaus

*Gaussian Correlation Structure*

---

**Description**

This function is a constructor for the `corGaus` class, representing a Gaussian spatial correlation structure. Letting  $d$  denote the range and  $n$  denote the nugget effect, the correlation between two observations a distance  $r$  apart is  $\exp(-(r/d)^2)$  when no nugget effect is present and  $(1-n)\exp(-(r/d)^2)$  when a nugget effect is assumed. Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

**Usage**

```
corGaus(value, form, nugget, metric, fixed)
```

**Arguments**

value	an optional vector with the parameter values in constrained form. If <code>nugget</code> is <code>FALSE</code> , <code>value</code> can have only one element, corresponding to the "range" of the Gaussian correlation structure, which must be greater than zero. If <code>nugget</code> is <code>TRUE</code> , meaning that a nugget effect is present, <code>value</code> can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to <code>numeric(0)</code> , which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when <code>object</code> is initialized.
form	a one sided formula of the form <code>~ S1+...+Sp</code> , or <code>~ S1+...+Sp   g</code> , specifying spatial covariates <code>S1</code> through <code>Sp</code> and, optionally, a grouping factor <code>g</code> . When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to <code>~ 1</code> , which corresponds to using the order of the observations in the data as a covariate, and no groups.
nugget	an optional logical value indicating whether a nugget effect is present. Defaults to <code>FALSE</code> .
metric	an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".
fixed	an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.

**Value**

an object of class `corGaus`, also inheriting from class `corSpatial`, representing a Gaussian spatial correlation structure.

corLin

*Linear Correlation Structure***Description**

This function is a constructor for the `corLin` class, representing a linear spatial correlation structure. Letting  $d$  denote the range and  $n$  denote the nugget effect, the correlation between two observations a distance  $r < d$  apart is  $1 - (r/d)$  when no nugget effect is present and  $(1 - n)(1 - (r/d))$  when a nugget effect is assumed. If  $r \geq d$  the correlation is zero. Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

**Usage**

```
corLin(value, form, nugget, metric, fixed)
```

**Arguments**

value	an optional vector with the parameter values in constrained form. If <code>nugget</code> is <code>FALSE</code> , <code>value</code> can have only one element, corresponding to the "range" of the linear correlation structure, which must be greater than zero. If <code>nugget</code> is <code>TRUE</code> , meaning that a nugget effect is present, <code>value</code> can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to <code>numeric(0)</code> , which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when <code>object</code> is initialized.
form	a one sided formula of the form $\sim S_1 + \dots + S_p$ , or $\sim S_1 + \dots + S_p \mid g$ , specifying spatial covariates $S_1$ through $S_p$ and, optionally, a grouping factor $g$ . When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups.
nugget	an optional logical value indicating whether a nugget effect is present. Defaults to <code>FALSE</code> .

<code>metric</code>	an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".
<code>fixed</code>	an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

### Value

an object of class `corLin`, also inheriting from class `corSpatial`, representing a linear spatial correlation structure.

```

---

corMatrix                      *Extract Correlation Matrix*

---

### Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all `corStruct` classes.

### Usage

```
corMatrix(object, ...)
```

### Arguments

`object`                      an object for which a correlation matrix can be extracted.  
`...`                              some methods for this generic function require additional arguments.

### Value

will depend on the method function used; see the appropriate documentation.

### Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates  
 <bates@stat.wisc.edu>

### See Also

[corMatrix.corStruct](#), [corMatrix.pdMat](#)

### Examples

```
## see the method function documentation
```

---

`corMatrix.corStruct`  
*Matrix of a corStruct Object*

---

### Description

This method function extracts the correlation matrix (or its transpose inverse square-root factor), or list of correlation matrices (or their transpose inverse square-root factors) corresponding to `covariate` and `object`. Letting  $\Sigma$  denote a correlation matrix, a square-root factor of  $\Sigma$  is any square matrix  $L$  such that  $\Sigma = L'L$ . When `corr = FALSE`, this method extracts  $L^{-t}$ .

### Usage

```
## S3 method for class 'corStruct':  
corMatrix(object, covariate, corr, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>corStruct</code> representing a correlation structure.
<code>covariate</code>	an optional covariate vector (matrix), or list of covariate vectors (matrices), at which values the correlation matrix, or list of correlation matrices, are to be evaluated. Defaults to <code>getCovariate(object)</code> .
<code>corr</code>	a logical value. If <code>TRUE</code> the function returns the correlation matrix, or list of correlation matrices, represented by <code>object</code> . If <code>FALSE</code> the function returns a transpose inverse square-root of the correlation matrix, or a list of transpose inverse square-root factors of the correlation matrices.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

If `covariate` is a vector (matrix), the returned value will be an array with the corresponding correlation matrix (or its transpose inverse square-root factor). If the `covariate` is a list of vectors (matrices), the returned value will be a list with the correlation matrices (or their transpose inverse square-root factors) corresponding to each component of `covariate`.

# Pinheiro and Bates, p. 238
spatDat <- data.frame(x = (0:4)/4, y = (0:4)/4)
cslExp <- corExp(1, form = ~ x + y)
cslExp <- Initialize(cslExp, spatDat)
corMatrix(cslExp)
```

---

corMatrix.pdMat      *Extract Correlation Matrix from a pdMat Object*

---

### Description

The correlation matrix corresponding to the positive-definite matrix represented by `object` is obtained.

### Usage

```
## S3 method for class 'pdMat':
corMatrix(object, ...)
```

### Arguments

<code>object</code>	an object inheriting from class <code>pdMat</code> , representing a positive definite matrix.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

### Value

the correlation matrix corresponding to the positive-definite matrix represented by `object`.

### Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

```

---

`corNatural`

*General correlation in natural parameterization*

---

### Description

This function is a constructor for the `corNatural` class, representing a general correlation structure in the “natural” parameterization, which is described under [pdNatural](#). Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

### Usage

```
corNatural(value, form, fixed)
```

**Arguments**

value	an optional vector with the parameter values. Default is <code>numeric(0)</code> , which results in a vector of zeros of appropriate dimension being assigned to the parameters when <code>object</code> is initialized (corresponding to an identity correlation structure).
form	a one sided formula of the form <code>~ t</code> , or <code>~ t   g</code> , specifying a time covariate <code>t</code> and, optionally, a grouping factor <code>g</code> . A covariate for this correlation structure must be integer valued. When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to <code>~ 1</code> , which corresponds to using the order of the observations in the data as a covariate, and no groups.
fixed	an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.

**Value**

an object of class `corNatural` representing a general correlation structure.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[Initialize.corNatural](#), [pdNatural](#), [summary.corNatural](#)

**Examples**

```
## covariate is observation order and grouping factor is Subject
csl <- corNatural(form = ~ 1 | Subject)
```

---

corRatio

*Rational Quadratic Correlation Structure*

---

**Description**

This function is a constructor for the `corRatio` class, representing a rational quadratic spatial correlation structure. Letting  $d$  denote the range and  $n$  denote the nugget effect, the correlation between two observations a distance  $r$  apart is  $1/(1 + (r/d)^2)$  when no nugget effect is present and  $(1 - n)/(1 + (r/d)^2)$  when a nugget effect is assumed. Objects created using this constructor need to be later initialized using the appropriate `Initialize` method.

**Usage**

```
corRatio(value, form, nugget, metric, fixed)
```

**Arguments**

value	an optional vector with the parameter values in constrained form. If <code>nugget</code> is <code>FALSE</code> , <code>value</code> can have only one element, corresponding to the "range" of the rational quadratic correlation structure, which must be greater than zero. If <code>nugget</code> is <code>TRUE</code> , meaning that a nugget effect is present, <code>value</code> can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to <code>numeric(0)</code> , which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when <code>object</code> is initialized.
form	a one sided formula of the form <code>~ S1+...+Sp</code> , or <code>~ S1+...+Sp   g</code> , specifying spatial covariates <code>S1</code> through <code>Sp</code> and, optionally, a grouping factor <code>g</code> . When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to <code>~ 1</code> , which corresponds to using the order of the observations in the data as a covariate, and no groups.
nugget	an optional logical value indicating whether a nugget effect is present. Defaults to <code>FALSE</code> .
metric	an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".
fixed	an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.

**Value**

an object of class `corRatio`, also inheriting from class `corSpatial`, representing a rational quadratic spatial correlation structure.

                          form = ~ latitude + longitude,
                          nugget = TRUE))

```

corSpatial

*Spatial Correlation Structure***Description**

This function is a constructor for the `corSpatial` class, representing a spatial correlation structure. This class is "virtual", having four "real" classes, corresponding to specific spatial correlation structures, associated with it: `corExp`, `corGaus`, `corLin`, `corRatio`, and `corSpher`. The returned object will inherit from one of these "real" classes, determined by the `type` argument, and from the "virtual" `corSpatial` class. Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

**Usage**

```
corSpatial(value, form, nugget, type, metric, fixed)
```

**Arguments**

`value` an optional vector with the parameter values in constrained form. If `nugget` is `FALSE`, `value` can have only one element, corresponding to the "range" of the spatial correlation structure, which must be greater than zero. If `nugget` is `TRUE`, meaning that a nugget effect is present, `value` can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to `numeric(0)`, which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when `object` is initialized.

form	a one sided formula of the form $\sim S_1 + \dots + S_p$ , or $\sim S_1 + \dots + S_p \mid g$ , specifying spatial covariates $S_1$ through $S_p$ and, optionally, a grouping factor $g$ . When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups.
nugget	an optional logical value indicating whether a nugget effect is present. Defaults to <code>FALSE</code> .
type	an optional character string specifying the desired type of correlation structure. Available types include "spherical", "exponential", "gaussian", "linear", and "rational". See the documentation on the functions <code>corSpher</code> , <code>corExp</code> , <code>corGaus</code> , <code>corLin</code> , and <code>corRatio</code> for a description of these correlation structures. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "spherical".
metric	an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".
fixed	an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.

### Value

an object of class determined by the `type` argument and also inheriting from class `corSpatial`, representing a spatial correlation structure.

corSpher

*Spherical Correlation Structure***Description**

This function is a constructor for the `corSpher` class, representing a spherical spatial correlation structure. Letting  $d$  denote the range and  $n$  denote the nugget effect, the correlation between two observations a distance  $r < d$  apart is  $1 - 1.5(r/d) + 0.5(r/d)^3$  when no nugget effect is present and  $(1 - n)(1 - 1.5(r/d) + 0.5(r/d)^3)$  when a nugget effect is assumed. If  $r \geq d$  the correlation is zero. Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

**Usage**

```
corSpher(value, form, nugget, metric, fixed)
```

**Arguments**

value	an optional vector with the parameter values in constrained form. If <code>nugget</code> is <code>FALSE</code> , <code>value</code> can have only one element, corresponding to the "range" of the spherical correlation structure, which must be greater than zero. If <code>nugget</code> is <code>TRUE</code> , meaning that a nugget effect is present, <code>value</code> can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to <code>numeric(0)</code> , which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when <code>object</code> is initialized.
form	a one sided formula of the form $\sim S_1 + \dots + S_p$ , or $\sim S_1 + \dots + S_p \mid g$ , specifying spatial covariates $S_1$ through $S_p$ and, optionally, a grouping factor $g$ . When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups.
nugget	an optional logical value indicating whether a nugget effect is present. Defaults to <code>FALSE</code> .
metric	an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".
fixed	an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.

**Value**

an object of class `corSpher`, also inheriting from class `corSpatial`, representing a spherical spatial correlation structure.

```

---

corSymm

*General Correlation Structure*

---

**Description**

This function is a constructor for the `corSymm` class, representing a general correlation structure. The internal representation of this structure, in terms of unconstrained parameters, uses the spherical parametrization defined in Pinheiro and Bates (1996). Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

**Usage**

```
corSymm(value, form, fixed)
```

**Arguments**

value	an optional vector with the parameter values. Default is <code>numeric(0)</code> , which results in a vector of zeros of appropriate dimension being assigned to the parameters when <code>object</code> is initialized (corresponding to an identity correlation structure).
form	a one sided formula of the form <code>~ t</code> , or <code>~ t   g</code> , specifying a time covariate <code>t</code> and, optionally, a grouping factor <code>g</code> . A covariate for this correlation structure must be integer valued. When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to <code>~ 1</code> , which corresponds to using the order of the observations in the data as a covariate, and no groups.
fixed	an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.

**Value**

an object of class `corSymm` representing a general correlation structure.

Covariate

*Assign Covariate Values*

---

### Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all `varFunc` classes.

### Usage

```
covariate(object) <- value
```

### Arguments

<code>object</code>	any object with a covariate component.
<code>value</code>	a value to be assigned to the covariate associated with <code>object</code> .

### Value

will depend on the method function; see the appropriate documentation.

### Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates  
<bates@stat.wisc.edu>

### See Also

### Examples

```
## see the method function documentation
```

---

Covariate.varFunc *Assign varFunc Covariate*

---

### Description

The covariate(s) used in the calculation of the weights of the variance function represented by object is (are) replaced by value. If object has been initialized, value must have the same dimensions as getCovariate(object).

### Usage

```
## S3 replacement method for class 'varFunc':  
covariate(object) <- value
```

### Arguments

object            an object inheriting from class varFunc, representing a variance function structure.  
value            a value to be assigned to the covariate associated with object.

### Value

a varFunc object similar to object, but with its covariate attribute replaced by value.

### Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

### See Also

[getCovariate.varFunc](#)

### Examples

```
vf1 <- varPower(1.1, form = ~age)  
covariate(vf1) <- Orthodont[["age"]]
```

---

Dialyzer

*High-Flux Hemodialyzer*

---

### Description

The Dialyzer data frame has 140 rows and 5 columns.

**Format**

This data frame contains the following columns:

**Subject** an ordered factor with levels 10 < 8 < 2 < 6 < 3 < 5 < 9 < 7 < 1 < 4 < 17 < 20 < 11 < 12 < 16 < 13 < 14 < 18 < 15 < 19 giving the unique identifier for each subject

**QB** a factor with levels 200 and 300 giving the bovine blood flow rate (dL/min).

**pressure** a numeric vector giving the transmembrane pressure (dmHg).

**rate** the hemodialyzer ultrafiltration rate (mL/hr).

**index** index of observation within subject—1 through 7.

**Details**

Vonesh and Carter (1992) describe data measured on high-flux hemodialyzers to assess their *in vivo* ultrafiltration characteristics. The ultrafiltration rates (in mL/hr) of 20 high-flux dialyzers were measured at seven different transmembrane pressures (in dmHg). The *in vitro* evaluation of the dialyzers used bovine blood at flow rates of either 200~dl/min or 300~dl/min. The data, are also analyzed in Littell, Milliken, Stroup, and Wolfinger (1996).

 Dim

---

*Extract Dimensions from an Object*

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `corSpatial`, `corStruct`, `pdCompSymm`, `pdDiag`, `pdIdent`, `pdMat`, and `pdSymm`.

**Usage**

```
Dim(object, ...)
```

**Arguments**

`object` any object for which dimensions can be extracted.  
`...` some methods for this generic function require additional arguments.

**Value**

will depend on the method function used; see the appropriate documentation.

**Note**

If `dim` allowed more than one argument, there would be no need for this generic function.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[Dim.pdMat](#), [Dim.corStruct](#)

**Examples**

```
## see the method function documentation
```

---

`Dim.corSpatial`      *Dimensions of a corSpatial Object*

---

**Description**

if `groups` is missing, it returns the `Dim` attribute of `object`; otherwise, calculates the dimensions associated with the grouping factor.

**Usage**

```
## S3 method for class 'corSpatial':
Dim(object, groups, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>corSpatial</code> , representing a spatial correlation structure.
<code>groups</code>	an optional factor defining the grouping of the observations; observations within a group are correlated and observations in different groups are uncorrelated.
<code>...</code>	further arguments to be passed to or from methods.

**Value**

a list with components:

<code>N</code>	length of <code>groups</code>
<code>M</code>	number of groups
<code>spClass</code>	an integer representing the spatial correlation class; 0 = user defined class, 1 = <code>corSpher</code> , 2 = <code>corExp</code> , 3 = <code>corGaus</code> , 4 = <code>corLin</code>
<code>sumLenSq</code>	sum of the squares of the number of observations per group
<code>len</code>	an integer vector with the number of observations per group
<code>start</code>	an integer vector with the starting position for the distance vectors in each group, beginning from zero

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates  
<bates@stat.wisc.edu>

**See Also**

Dim(corGaus(), getGroups(Orthodont))

cslARMA <- corARMA(0.4, form = ~ 1 | Subject, q = 1)
cslARMA <- Initialize(cslARMA, data = Orthodont)
Dim(cslARMA)
```

---

Dim.corStruct

*Dimensions of a corStruct Object*

---

**Description**

if `groups` is missing, it returns the `Dim` attribute of `object`; otherwise, calculates the dimensions associated with the grouping factor.

**Usage**

```
## S3 method for class 'corStruct':
Dim(object, groups, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>corStruct</code> , representing a correlation structure.
<code>groups</code>	an optional factor defining the grouping of the observations; observations within a group are correlated and observations in different groups are uncorrelated.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a list with components:

<code>N</code>	length of <code>groups</code>
<code>M</code>	number of groups
<code>maxLen</code>	maximum number of observations in a group
<code>sumLenSq</code>	sum of the squares of the number of observations per group
<code>len</code>	an integer vector with the number of observations per group
<code>start</code>	an integer vector with the starting position for the observations in each group, beginning from zero

**Author(s)**

Dim.pdMat

*Dimensions of a pdMat Object*

---

**Description**

This method function returns the dimensions of the matrix represented by `object`.

**Usage**

```
## S3 method for class 'pdMat':  
Dim(object, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>pdMat</code> , representing a positive-definite matrix.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

an integer vector with the number of rows and columns of the matrix represented by `object`.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates  
<bates@stat.wisc.edu>

**See Also**

```

---

 Earthquake

*Earthquake Intensity*

---

### Description

The Earthquake data frame has 182 rows and 5 columns.

### Format

This data frame contains the following columns:

**Quake** an ordered factor with levels 20 < 16 < 14 < 10 < 3 < 8 < 23 < 22 < 6 < 13 < 7 < 21 < 18 < 15 < 4 < 12 < 19 < 5 < 9 < 1 < 2 < 17 < 11 indicating the earthquake on which the measurements were made.

**Richter** a numeric vector giving the intensity of the earthquake on the Richter scale.

**distance** the distance from the seismological measuring station to the epicenter of the earthquake (km).

**soil** a factor with levels 0 and 1 giving the soil condition at the measuring station, either soil or rock.

**accel** maximum horizontal acceleration observed (g).

### Details

Measurements recorded at available seismometer locations for 23 large earthquakes in western North America between 1940 and 1980. They were originally given in Joyner and Boore (1981); are mentioned in Brillinger (1987); and are analyzed in Davidian and Giltinan (1995).

---

 ergoStool

*Ergometrics experiment with stool types*

---

### Description

The ergoStool data frame has 36 rows and 3 columns.

**Format**

This data frame contains the following columns:

**effort** a numeric vector giving the effort (Borg scale) required to arise from a stool.

**Type** a factor with levels T1, T2, T3, and T4 giving the stool type.

**Subject** an ordered factor giving a unique identifier for the subject in the experiment.

**Details**

Devore (2000) cites data from an article in *Ergometrics* (1993, pp. 519-535) on “The Effects of a Pneumatic Stool and a One-Legged Stool on Lower Limb Joint Load and Muscular Activity.”

**Examples**

```
fml <-
  lme(effort ~ Type, data = ergoStool, random = ~ 1 | Subject)
anova( fml )
```

---

Fatigue

*Cracks caused by metal fatigue*

---

**Description**

The `Fatigue` data frame has 262 rows and 3 columns.

**Format**

This data frame contains the following columns:

**Path** an ordered factor with levels 1 < 2 < 3 < 4 < 5 < 6 < 7 < 8 < 9 < 10 < 11 < 12 < 13 < 14 < 15 < 16 < 17 < 18 < 19 < 20 < 21 giving the test path (or test unit) number. The order is in terms of increasing failure time or decreasing terminal crack length.

**cycles** number of test cycles at which the measurement is made (millions of cycles).

**relLength** relative crack length (dimensionless).

**Details**

These data are given in Lu and Meeker (1993) where they state “We obtained the data in Table 1 visually from figure 4.5.2 on page 242 of Bogdanoff and Kozin (1985).” The data represent the growth of cracks in metal for 21 test units. An initial notch of length 0.90 inches was made on each unit which then was subjected to several thousand test cycles. After every 10,000 test cycles the crack length was measured. Testing was stopped if the crack length exceeded 1.60 inches, defined as a failure, or at 120,000 cycles.

fdHess

*Finite difference Hessian***Description**

Evaluate an approximate Hessian and gradient of a scalar function using finite differences.

**Usage**

```
fdHess(pars, fun, ..., .relStep=(.Machine$double.eps)^(1/3), minAbsPar=0)
```

**Arguments**

pars	the numeric values of the parameters at which to evaluate the function <code>fun</code> and its derivatives.
fun	a function depending on the parameters <code>pars</code> that returns a numeric scalar.
...	Optional additional arguments to <code>fun</code>
.relStep	The relative step size to use in the finite differences. It defaults to the cube root of <code>.Machine\$double.eps</code>
minAbsPar	The minimum magnitude of a parameter value that is considered non-zero. It defaults to zero meaning that any non-zero value will be considered different from zero.

**Details**

This function uses a second-order response surface design known as a Koschal design to determine the parameter values at which the function is evaluated.

**Value**

A list with components

mean	the value of function <code>fun</code> evaluated at the parameter values <code>pars</code>
gradient	an approximate gradient
Hessian	a matrix whose upper triangle contains an approximate Hessian.

**Author(s)**

Jose Pinheiro	<jcp@research.bell-labs.com>	Douglas Bates	<bates@stat.wisc.edu>
---------------	------------------------------	---------------	-----------------------

**Examples**

```
fdHess(c(12.3, 2.34), function(x) x[1]*(1-exp(-0.4*x[2])))
```

---

fitted.glsStruct     *Calculate glsStruct Fitted Values*

---

### Description

The fitted values for the linear model represented by `object` are extracted.

### Usage

```
## S3 method for class 'glsStruct':  
fitted(object, glsFit, ...)
```

### Arguments

<code>object</code>	an object inheriting from class <code>glsStruct</code> , representing a list of linear model components, such as <code>corStruct</code> and <code>varFunc</code> objects.
<code>glsFit</code>	an optional list with components <code>logLik</code> (log-likelihood), <code>beta</code> (coefficients), <code>sigma</code> (standard deviation for error term), <code>varBeta</code> (coefficients' covariance matrix), <code>fitted</code> (fitted values), and <code>residuals</code> (residuals). Defaults to <code>attr(object, "glsFit")</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

### Value

a vector with the fitted values for the linear model represented by `object`.

### Note

This method function is generally only used inside `gls` and `fitted.gls`.

### Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates  
<bates@stat.wisc.edu>

### See Also

[gls](#), [residuals.glsStruct](#)

---

fitted.gnlsStruct    *Calculate gnlsStruct Fitted Values*

---

### Description

The fitted values for the nonlinear model represented by `object` are extracted.

### Usage

```
## S3 method for class 'gnlsStruct':
fitted(object, ...)
```

### Arguments

<code>object</code>	an object inheriting from class <code>gnlsStruct</code> , representing a list of model components, such as <code>corStruct</code> and <code>varFunc</code> objects, and attributes specifying the underlying nonlinear model and the response variable.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

### Value

a vector with the fitted values for the nonlinear model represented by `object`.

### Note

This method function is generally only used inside `gnls` and `fitted.gnls`.

### Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

---

fitted.lme    *Extract lme Fitted Values*

---

### Description

The fitted values at level  $i$  are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to  $i$ . The resulting values estimate the best linear unbiased predictions (BLUPs) at level  $i$ .

### Usage

```
## S3 method for class 'lme':
fitted(object, level, asList, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>lme</code> , representing a fitted linear mixed-effects model.
<code>level</code>	an optional integer vector giving the level(s) of grouping to be used in extracting the fitted values from <code>object</code> . Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.
<code>asList</code>	an optional logical value. If <code>TRUE</code> and a single value is given in <code>level</code> , the returned object is a list with the fitted values split by groups; else the returned value is either a vector or a data frame, according to the length of <code>level</code> . Defaults to <code>FALSE</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

If a single level of grouping is specified in `level`, the returned value is either a list with the fitted values split by groups (`asList = TRUE`) or a vector with the fitted values (`asList = FALSE`); else, when multiple grouping levels are specified in `level`, the returned object is a data frame with columns given by the fitted values at different levels and the grouping factors. For a vector or data frame result the `napredict` method is applied.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**References**

fml <- lme(distance ~ age + Sex, data = Orthodont, random = ~ 1)
fitted(fml, level = 0:1)
```

---

fitted.lmeStruct    *Calculate lmeStruct Fitted Values*

---

### Description

The fitted values at level  $i$  are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to  $i$ . The resulting values estimate the best linear unbiased predictions (BLUPs) at level  $i$ .

### Usage

```
## S3 method for class 'lmeStruct':
fitted(object, level, conLin, lmeFit, ...)
```

### Arguments

object	an object inheriting from class <code>lmeStruct</code> , representing a list of linear mixed-effects model components, such as <code>reStruct</code> , <code>corStruct</code> , and <code>varFunc</code> objects.
level	an optional integer vector giving the level(s) of grouping to be used in extracting the fitted values from <code>object</code> . Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.
conLin	an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying lme model. Defaults to <code>attr(object, "conLin")</code> .
lmeFit	an optional list with components <code>beta</code> and <code>b</code> containing respectively the fixed effects estimates and the random effects estimates to be used to calculate the fitted values. Defaults to <code>attr(object, "lmeFit")</code> .
...	some methods for this generic accept other optional arguments.

### Value

if a single level of grouping is specified in `level`, the returned value is a vector with the fitted values at the desired level; else, when multiple grouping levels are specified in `level`, the returned object is a matrix with columns given by the fitted values at different levels.

### Note

This method function is generally only used inside `lme` and `fitted.lme`.

fitted.lmList      *Extract lmList Fitted Values*

---

### Description

The fitted values are extracted from each `lm` component of `object` and arranged into a list with as many components as `object`, or combined into a single vector.

### Usage

```
## S3 method for class 'lmList':  
fitted(object, subset, asList, ...)
```

### Arguments

<code>object</code>	an object inheriting from class <code>lmList</code> , representing a list of <code>lm</code> objects with a common model.
<code>subset</code>	an optional character or integer vector naming the <code>lm</code> components of <code>object</code> from which the fitted values are to be extracted. Default is <code>NULL</code> , in which case all components are used.
<code>asList</code>	an optional logical value. If <code>TRUE</code> , the returned object is a list with the fitted values split by groups; else the returned value is a vector. Defaults to <code>FALSE</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

### Value

a list with components given by the fitted values of each `lm` component of `object`, or a vector with the fitted values for all `lm` components of `object`.

### Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

### See Also

[lmList](#), [residuals.lmList](#)

### Examples

fml <- lmList(distance ~ age | Subject, Orthodont)  
fitted(fml)
```

---

fitted.nlmeStruct *Calculate nlmeStruct Fitted Values*

---

### Description

The fitted values at level  $i$  are obtained by adding together the contributions from the estimated fixed effects and the estimated random effects at levels less or equal to  $i$  and evaluating the model function at the resulting estimated parameters. The resulting values estimate the predictions at level  $i$ .

### Usage

```
## S3 method for class 'nlmeStruct':
fitted(object, level, conLin, ...)
```

### Arguments

object	an object inheriting from class <code>nlmeStruct</code> , representing a list of mixed-effects model components, such as <code>reStruct</code> , <code>corStruct</code> , and <code>varFunc</code> objects, plus attributes specifying the underlying nonlinear model and the response variable.
level	an optional integer vector giving the level(s) of grouping to be used in extracting the fitted values from <code>object</code> . Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.
conLin	an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying nlme model. Defaults to <code>attr(object, "conLin")</code> .
...	additional arguments that could be given to this method. None are used.

### Value

if a single level of grouping is specified in `level`, the returned value is a vector with the fitted values at the desired level; else, when multiple grouping levels are specified in `level`, the returned object is a matrix with columns given by the fitted values at different levels.

### Note

This method function is generally only used inside `nlme` and `fitted.nlme`.

```

---

`fixef.lmList`      *Extract lmList Fixed Effects*

---

### Description

The average of the coefficients corresponding to the `lm` components of `object` is calculated.

### Usage

```
## S3 method for class 'lmList':  
fixef(object, ...)
```

### Arguments

`object`      an object inheriting from class `lmList`, representing a list of `lm` objects with a common model.

`...`      some methods for this generic require additional arguments. None are used in this method.

### Value

a vector with the average of the individual `lm` coefficients in `object`.

### Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

### See Also

fixed.effects(fm1)
```

---

`formula.pdBlocked`      *Extract pdBlocked Formula*

---

### Description

The `formula` attributes of the `pdMat` elements of `x` are extracted and returned as a list, in case `asList=TRUE`, or converted to a single one-sided formula when `asList=FALSE`. If the `pdMat` elements do not have a `formula` attribute, a `NULL` value is returned.

### Usage

```
## S3 method for class 'pdBlocked':  
formula(x, asList, ...)
```

**Arguments**

<code>x</code>	an object inheriting from class <code>pdBlocked</code> , representing a positive definite block diagonal matrix.
<code>asList</code>	an optional logical value. If <code>TRUE</code> , a list with the formulas for the individual block diagonal elements of <code>x</code> is returned; else, if <code>FALSE</code> , a one-sided formula combining all individual formulas is returned. Defaults to <code>FALSE</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a list of one-sided formulas, or a single one-sided formula, or `NULL`.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

pd1 <- pdBlocked(list(~ age, ~ Sex - 1))
formula(pd1)
formula(pd1, asList = TRUE)
```

---

formula.pdMat	<i>Extract pdMat Formula</i>
---------------	------------------------------

---

**Description**

This method function extracts the formula associated with a `pdMat` object, in which the column and row names are specified.

**Usage**

```
## S3 method for class 'pdMat':
formula(x, asList, ...)
```

**Arguments**

<code>x</code>	an object inheriting from class <code>pdMat</code> , representing a positive definite matrix.
<code>asList</code>	logical. Should the <code>asList</code> argument be applied to each of the components? Never used.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

if `x` has a `formula` attribute, its value is returned, else `NULL` is returned.

**Note**

Because factors may be present in `formula(x)`, the `pdMat` object needs to have access to a data frame where the variables named in the formula can be evaluated, before it can resolve its row and column names from the formula.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

---

`formula.reStruct`     *Extract reStruct Object Formula*

---

**Description**

This method function extracts a formula from each of the components of `x`, returning a list of formulas.

**Usage**

```
## S3 method for class 'reStruct':
formula(x, asList, ...)
```

**Arguments**

<code>x</code>	an object inheriting from class <code>reStruct</code> , representing a random effects structure and consisting of a list of <code>pdMat</code> objects.
<code>asList</code>	logical. Should the <code>asList</code> argument be applied to each of the components?
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a list with the formulas of each component of `x`.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

formula(rs1)
```

---

gapply

*Apply a Function by Groups*

---

**Description**

Applies the function to the distinct sets of rows of the data frame defined by groups.

**Usage**

```
gapply(object, which, FUN, form, level, groups, ...)
```

**Arguments**

object	an object to which the function will be applied - usually a <code>groupedData</code> object or a <code>data.frame</code> . Must inherit from class <code>data.frame</code> .
which	an optional character or positive integer vector specifying which columns of <code>object</code> should be used with <code>FUN</code> . Defaults to all columns in <code>object</code> .
FUN	function to apply to the distinct sets of rows of the data frame <code>object</code> defined by the values of <code>groups</code> .
form	an optional one-sided formula that defines the groups. When this formula is given the right-hand side is evaluated in <code>object</code> , converted to a factor if necessary, and the unique levels are used to define the groups. Defaults to <code>formula(object)</code> .
level	an optional positive integer giving the level of grouping to be used in an object with multiple nested grouping levels. Defaults to the highest or innermost level of grouping.
groups	an optional factor that will be used to split the rows into groups. Defaults to <code>getGroups(object, form, level)</code> .
...	optional additional arguments to the summary function <code>FUN</code> . Often it is helpful to specify <code>na.rm = TRUE</code> .

**Value**

Returns a data frame with as many rows as there are levels in the `groups` argument.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

table( gapply(Quinidine, "conc", function(x) sum(!is.na(x))) )
changeRecords <- gapply( Quinidine, FUN = function(frm)
  any(is.na(frm[["conc"]]) & is.na(frm[["dose"]])) ) )
```

---

Gasoline

*Refinery yield of gasoline*

---

## Description

The Gasoline data frame has 32 rows and 6 columns.

## Format

This data frame contains the following columns:

**yield** a numeric vector giving the percentage of crude oil converted to gasoline after distillation and fractionation

**endpoint** a numeric vector giving the temperature (degrees F) at which all the gasoline is vaporized

**Sample** an ordered factor giving the inferred crude oil sample number

**API** a numeric vector giving the crude oil gravity (degrees API)

**vapor** a numeric vector giving the vapor pressure of the crude oil (lbf/in<sup>2</sup>)

**ASTM** a numeric vector giving the crude oil 10% point ASTM—the temperature at which 10% of the crude oil has become vapor.

## Details

Prater (1955) provides data on crude oil properties and gasoline yields. Atkinson (1985) uses these data to illustrate the use of diagnostics in multiple regression analysis. Three of the covariates—API, vapor, and ASTM—measure characteristics of the crude oil used to produce the gasoline. The other covariate — endpoint—is a characteristic of the refining process. Daniel and Wood (1980) notice that the covariates characterizing the crude oil occur in only ten distinct groups and conclude that the data represent responses measured on ten different crude oil samples.

getCovariate	<i>Extract Covariate from an Object</i>
--------------	---

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `corStruct`, `corSpatial`, `data.frame`, and `varFunc`.

**Usage**

```
getCovariate(object, form, data)
```

**Arguments**

<code>object</code>	any object with a <code>covariate</code> component
<code>form</code>	an optional one-sided formula specifying the covariate(s) to be extracted. Defaults to <code>formula(object)</code> .
<code>data</code>	a data frame in which to evaluate the variables defined in <code>form</code> .

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**References**

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer, esp. p. 100.

```

---

`getCovariate.corStruct`*Extract corStruct Object Covariate*

---

## Description

This method function extracts the covariate(s) associated with `object`.

## Usage

```
## S3 method for class 'corStruct':  
getCovariate(object, form, data)
```

## Arguments

<code>object</code>	an object inheriting from class <code>corStruct</code> representing a correlation structure.
<code>form</code>	this argument is included to make the method function compatible with the generic. It will be assigned the value of <code>formula(object)</code> and should not be modified.
<code>data</code>	an optional data frame in which to evaluate the variables defined in <code>form</code> , in case <code>object</code> is not initialized and the covariate needs to be evaluated.

## Value

when the correlation structure does not include a grouping factor, the returned value will be a vector or a matrix with the covariate(s) associated with `object`. If a grouping factor is present, the returned value will be a list of vectors or matrices with the covariate(s) corresponding to each grouping level.

getCovariate(cs1, data = Orthodont)
```

---

```
getCovariate.data.frame
```

*Extract Data Frame Covariate*

---

### Description

The right hand side of `form`, stripped of any conditioning expression (i.e. an expression following a `|` operator), is evaluated in `object`.

### Usage

```
## S3 method for class 'data.frame':  
getCovariate(object, form, data)
```

### Arguments

<code>object</code>	an object inheriting from class <code>data.frame</code> .
<code>form</code>	an optional formula specifying the covariate to be evaluated in <code>object</code> . Defaults to <code>formula(object)</code> .
<code>data</code>	some methods for this generic require a separate data frame. Not used in this method.

### Value

the value of the right hand side of `form`, stripped of any conditional expression, evaluated in `object`.

### Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

### See Also

---

`getCovariate.varFunc`*Extract varFunc Covariate*

---

### Description

This method function extracts the covariate(s) associated with the variance function represented by `object`, if any is present.

### Usage

```
## S3 method for class 'varFunc':  
getCovariate(object, form, data)
```

### Arguments

<code>object</code>	an object inheriting from class <code>varFunc</code> , representing a variance function structure.
<code>form</code>	an optional formula specifying the covariate to be evaluated in <code>object</code> . Defaults to <code>formula(object)</code> .
<code>data</code>	some methods for this generic require a <code>data</code> object. Not used in this method.

### Value

if `object` has a `covariate` attribute, its value is returned; else `NULL` is returned.

### Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates  
<bates@stat.wisc.edu>

```

---

```
getCovariateFormula
```

*Extract Covariates Formula*

---

**Description**

The right hand side of `formula(object)`, without any conditioning expressions (i.e. any expressions after a `|` operator) is returned as a one-sided formula.

**Usage**

```
getCovariateFormula(object)
```

**Arguments**

`object` any object from which a formula can be extracted.

**Value**

a one-sided formula describing the covariates associated with `formula(object)`.

getGroups

*Extract Grouping Factors from an Object*

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `corStruct`, `data.frame`, `gls`, `lme`, `lmList`, and `varFunc`.

**Usage**

```
getGroups(object, form, level, data, sep)
```

**Arguments**

`object` any object

`form` an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the `|` operator). Defaults to `formula(object)`.

`level` a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting.

`data` a data frame in which to interpret the variables named in `form`. Optional for most methods.

`sep` character, the separator to use between group levels when multiple levels are collapsed. The default is `' / '`.

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates  
<bates@stat.wisc.edu>

```
getGroups.corStruct
      Extract corStruct Groups
```

---

**Description**

This method function extracts the grouping factor associated with `object`, if any is present.

**Usage**

```
## S3 method for class 'corStruct':
getGroups(object, form, level, data, sep)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>corStruct</code> representing a correlation structure.
<code>form</code>	this argument is included to make the method function compatible with the generic. It will be assigned the value of <code>formula(object)</code> and should not be modified.
<code>level</code>	this argument is included to make the method function compatible with the generic and is not used.
<code>data</code>	an optional data frame in which to evaluate the variables defined in <code>form</code> , in case <code>object</code> is not initialized and the grouping factor needs to be evaluated.
<code>sep</code>	character, the separator to use between group levels when multiple levels are collapsed. The default is <code>'/'</code> .

**Value**

if a grouping factor is present in the correlation structure represented by `object`, the function returns the corresponding factor vector; else the function returns `NULL`.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[getGroups](#)

**Examples**

```
cs1 <- corAR1(form = ~ 1 | Subject)
getGroups(cs1, data = Orthodont)
```

---

```
getGroups.data.frame
```

*Extract Groups from a Data Frame*

---

**Description**

Each variable named in the expression after the `|` operator on the right hand side of `form` is evaluated in `object`. If more than one variable is indicated in `level` they are combined into a data frame; else the selected variable is returned as a vector. When multiple grouping levels are defined in `form` and `level > 1`, the levels of the returned factor are obtained by pasting together the levels of the grouping factors of level greater or equal to `level`, to ensure their uniqueness.

**Usage**

```
## S3 method for class 'data.frame':
getGroups(object, form, level, data, sep)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>data.frame</code> .
<code>form</code>	an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the <code> </code> operator). Defaults to <code>formula(object)</code> .
<code>level</code>	a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. Defaults to all levels of nesting.
<code>data</code>	unused
<code>sep</code>	character, the separator to use between group levels when multiple levels are collapsed. The default is <code>'/'</code> .

**Value**

either a data frame with columns given by the grouping factors indicated in `level`, from outer to inner, or, when a single level is requested, a factor representing the selected grouping factor.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

  random = list(Dog = ~day, Side = ~1))
getGroups(fml, level = 1:2)
```

---

getGroups.lmList     *Extract lmList Object Groups*

---

**Description**

The grouping factor determining the partitioning of the observations used to produce the `lm` components of `object` is extracted.

**Usage**

```
## S3 method for class 'lmList':
getGroups(object, form, level, data, sep)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>lmList</code> , representing a list of <code>lm</code> objects with a common model.
<code>form</code>	an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the <code> </code> operator). Defaults to <code>formula(object)</code> . Not used.
<code>level</code>	a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting. Not used.
<code>data</code>	a data frame in which to interpret the variables named in <code>form</code> . Optional for most methods. Not used.
<code>sep</code>	character, the separator to use between group levels when multiple levels are collapsed. The default is <code>'/'</code> . Not used.

**Value**

a vector with the grouping factor corresponding to the `lm` components of `object`.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**[lmList](#)

## Examples

```
fml <- lmList(distance ~ age | Subject, Orthodont)
getGroups(fml)
```

---

getGroups.varFunc *Extract varFunc Groups*

---

## Description

This method function extracts the grouping factor associated with the variance function represented by `object`, if any is present.

## Usage

```
## S3 method for class 'varFunc':
getGroups(object, form, level, data, sep)
```

## Arguments

<code>object</code>	an object inheriting from class <code>varFunc</code> , representing a variance function structure.
<code>form</code>	an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the <code> </code> operator). Defaults to <code>formula(object)</code> . Not used.
<code>level</code>	a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting. Not used.
<code>data</code>	a data frame in which to interpret the variables named in <code>form</code> . Optional for most methods. Not used.
<code>sep</code>	character, the separator to use between group levels when multiple levels are collapsed. The default is <code>'/'</code> . Not used.

## Value

if `object` has a `groups` attribute, its value is returned; else `NULL` is returned.

## Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

## Examples

```
vf1 <- varPower(form = ~ age | Sex)
vf1 <- Initialize(vf1, Orthodont)
getGroups(vf1)
```

---

getGroupsFormula     *Extract Grouping Formula*

---

### Description

The conditioning expression associated with `formula(object)` (i.e. the expression after the `|` operator) is returned either as a named list of one-sided formulas, or a single one-sided formula, depending on the value of `asList`. The components of the returned list are ordered from outermost to innermost level and are named after the grouping factor expression.

### Usage

```
getGroupsFormula(object, asList, sep)
```

### Arguments

<code>object</code>	any object from which a formula can be extracted.
<code>asList</code>	an optional logical value. If <code>TRUE</code> the returned value will be a list of formulas; else, if <code>FALSE</code> the returned value will be a one-sided formula. Defaults to <code>FALSE</code> .
<code>sep</code>	character, the separator to use between group levels when multiple levels are collapsed. The default is <code>'/'</code> .

### Value

a one-sided formula, or a list of one-sided formulas, with the grouping structure associated with `formula(object)`. If no conditioning expression is present in `formula(object)` a `NULL` value is returned.

### Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates  
<bates@stat.wisc.edu>

getResponseFormula    *Extract Formula Specifying Response Variable*

---

**Description**

The left hand side of `formula{object}` is returned as a one-sided formula.

**Usage**

```
getResponseFormula(object)
```

**Arguments**

`object`                    any object from which a formula can be extracted.

**Value**

a one-sided formula with the response variable associated with `formula{object}`.

---

getVarCov	<i>Extract variance-covariance matrix</i>
-----------	---

---

**Description**

Extract the variance-covariance matrix from a fitted model, such as a mixed-effects model.

**Usage**

```
getVarCov(obj, ...)
## S3 method for class 'lme':
getVarCov(obj, individuals,
          type = c("random.effects", "conditional", "marginal"), ...)
## S3 method for class 'gls':
getVarCov(obj, individual = 1, ...)
```

**Arguments**

obj	A fitted model. Methods are available for models fit by <a href="#">lme</a> and by <a href="#">gls</a>
individuals	For models fit by <a href="#">lme</a> a vector of levels of the grouping factor can be specified for the conditional or marginal variance-covariance matrices.
individual	For models fit by <a href="#">gls</a> the only type of variance-covariance matrix provided is the marginal variance-covariance of the responses by group. The optional argument <code>individual</code> specifies the group of responses.
type	For models fit by <a href="#">lme</a> the <code>type</code> argument specifies the type of variance-covariance matrix, either <code>"random.effects"</code> for the random-effects variance-covariance (the default), or <code>"conditional"</code> for the conditional variance-covariance of the responses or <code>"marginal"</code> for the the marginal variance-covariance of the responses.
...	Optional arguments for some methods, as described above

**Value**

A variance-covariance matrix or a list of variance-covariance matrices.

gls

*Fit Linear Model Using Generalized Least Squares*

---

**Description**

This function fits a linear model using generalized least squares. The errors are allowed to be correlated and/or have unequal variances.

**Usage**

```
gls(model, data, correlation, weights, subset, method, na.action,
     control, verbose)
## S3 method for class 'gls':
update(object, model., ..., evaluate = TRUE)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>gls</code> , representing a generalized least squares fitted linear model.
<code>model</code>	a two-sided linear formula object describing the model, with the response on the left of a <code>~</code> operator and the terms, separated by <code>+</code> operators, on the right.
<code>model.</code>	Changes to the model – see <code>update.formula</code> for details.
<code>data</code>	an optional data frame containing the variables named in <code>model</code> , <code>correlation</code> , <code>weights</code> , and <code>subset</code> . By default the variables are taken from the environment from which <code>gls</code> is called.
<code>correlation</code>	an optional <code>corStruct</code> object describing the within-group correlation structure. See the documentation of <code>corClasses</code> for a description of the available <code>corStruct</code> classes. If a grouping variable is to be used, it must be specified in the <code>form</code> argument to the <code>corStruct</code> constructor. Defaults to <code>NULL</code> , corresponding to uncorrelated errors.

<code>weights</code>	an optional <code>varFunc</code> object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to <code>varFixed</code> , corresponding to fixed variance weights. See the documentation on <code>varClasses</code> for a description of the available <code>varFunc</code> classes. Defaults to <code>NULL</code> , corresponding to homoscedastic errors.
<code>subset</code>	an optional expression indicating which subset of the rows of <code>data</code> should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
<code>method</code>	a character string. If <code>"REML"</code> the model is fit by maximizing the restricted log-likelihood. If <code>"ML"</code> the log-likelihood is maximized. Defaults to <code>"REML"</code> .
<code>na.action</code>	a function that indicates what should happen when the data contain <code>NA</code> s. The default action ( <code>na.fail</code> ) causes <code>gls</code> to print an error message and terminate if there are any incomplete observations.
<code>control</code>	a list of control values for the estimation algorithm to replace the default values returned by the function <code>glsControl</code> . Defaults to an empty list.
<code>verbose</code>	an optional logical value. If <code>TRUE</code> information on the evolution of the iterative algorithm is printed. Default is <code>FALSE</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.
<code>evaluate</code>	If <code>TRUE</code> evaluate the new call else return the call.

### Value

an object of class `gls` representing the linear model fit. Generic functions such as `print`, `plot`, and `summary` have methods to show the results of the fit. See `glsObject` for the components of the fit. The functions `resid`, `coef`, and `fitted` can be used to extract some of its components.

# variance increases as a power of the absolute fitted values
fm2 <- update(fm1, weights = varPower())
```

---

glsControl

*Control Values for gls Fit*

---

### Description

The values supplied in the function call replace the defaults and a list with all possible arguments is returned. The returned list is used as the `control` argument to the `gls` function.

### Usage

```
glsControl(maxIter, msMaxIter, tolerance, msTol, msScale, msVerbose,
           singular.ok, qrTol, returnObject, apVar, .relStep,
           nlmStepMax, opt=c("nlminb", "optim"), optimMethod,
           minAbsParApVar, natural)
```

### Arguments

<code>maxIter</code>	maximum number of iterations for the <code>gls</code> optimization algorithm. Default is 50.
<code>msMaxIter</code>	maximum number of iterations for the optimization step inside the <code>gls</code> optimization. Default is 50.
<code>tolerance</code>	tolerance for the convergence criterion in the <code>gls</code> algorithm. Default is 1e-6.
<code>msTol</code>	tolerance for the convergence criterion in <code>ms</code> , passed as the <code>rel.tolerance</code> argument to the function (see documentation on <code>ms</code> ). Default is 1e-7.
<code>msScale</code>	scale function passed as the <code>scale</code> argument to the <code>ms</code> function (see documentation on that function). Default is <code>lmeScale</code> .
<code>msVerbose</code>	a logical value passed as the <code>trace</code> argument to <code>ms</code> (see documentation on that function). Default is <code>FALSE</code> .
<code>singular.ok</code>	a logical value indicating whether non-estimable coefficients (resulting from linear dependencies among the columns of the regression matrix) should be allowed. Default is <code>FALSE</code> .
<code>qrTol</code>	a tolerance for detecting linear dependencies among the columns of the regression matrix in its QR decomposition. Default is <code>.Machine\$single.eps</code> .

returnObject	a logical value indicating whether the fitted object should be returned when the maximum number of iterations is reached without convergence of the algorithm. Default is FALSE.
apVar	a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is TRUE.
.relStep	relative step for numerical derivatives calculations. Default is $.Machine\$double.eps^{(1/3)}$ .
nlmStepMax	stepmax value to be passed to nlm. See <a href="#">nlm</a> for details. Default is 100.0
opt	the optimizer to be used, either <a href="#">nlminb</a> (the default since (R 2.2.0) or <a href="#">optim</a> (the previous default).
optimMethod	character - the optimization method to be used with the <a href="#">optim</a> optimizer. The default is "BFGS". An alternative is "L-BFGS-B".
minAbsParApVar	numeric value - minimum absolute parameter value in the approximate variance calculation. The default is 0.05.
natural	logical. Should the natural parameterization be used for the approximate variance calculations? Default is TRUE.

**Value**

a list with components for each of the possible arguments.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[gls](#), [lmeScale](#)

**Examples**

# request that information on the evolution of the ms iterations be printed
glsControl(msMaxIter = 20, msVerbose = TRUE)
```

---

glsObject

*Fitted gls Object*

---

**Description**

An object returned by the `gls` function, inheriting from class `gls` and representing a generalized least squares fitted linear model. Objects of this class have methods for the generic functions `anova`, `coef`, `fitted`, `formula`, `getGroups`, `getResponse`, `intervals`, `logLik`, `plot`, `predict`, `print`, `residuals`, `summary`, and `update`.

**Value**

The following components must be included in a legitimate `gls` object.

<code>apVar</code>	an approximate covariance matrix for the variance-covariance coefficients. If <code>apVar = FALSE</code> in the list of control values used in the call to <code>gls</code> , this component is equal to <code>NULL</code> .
<code>call</code>	a list containing an image of the <code>gls</code> call that produced the object.
<code>coefficients</code>	a vector with the estimated linear model coefficients.
<code>contrasts</code>	a list with the contrasts used to represent factors in the model formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the model, this component will be an empty list.
<code>dims</code>	a list with basic dimensions used in the model fit, including the components <code>N</code> - the number of observations in the data and <code>p</code> - the number of coefficients in the linear model.
<code>fitted</code>	a vector with the fitted values..
<code>glsStruct</code>	an object inheriting from class <code>glsStruct</code> , representing a list of linear model components, such as <code>corStruct</code> and <code>varFunc</code> objects.
<code>groups</code>	a vector with the correlation structure grouping factor, if any is present.
<code>logLik</code>	the log-likelihood at convergence.
<code>method</code>	the estimation method: either "ML" for maximum likelihood, or "REML" for restricted maximum likelihood.
<code>numIter</code>	the number of iterations used in the iterative algorithm.
<code>residuals</code>	a vector with the residuals.
<code>sigma</code>	the estimated residual standard error.
<code>varBeta</code>	an approximate covariance matrix of the coefficients estimates.

`glsStruct`

*Generalized Least Squares Structure*

---

**Description**

A generalized least squares structure is a list of model components representing different sets of parameters in the linear model. A `glsStruct` may contain `corStruct` and `varFunc` objects. `NULL` arguments are not included in the `glsStruct` list.

**Usage**

```
glsStruct(corStruct, varStruct)
```

**Arguments**

- `corStruct` an optional `corStruct` object, representing a correlation structure. Default is `NULL`.
- `varStruct` an optional `varFunc` object, representing a variance function structure. Default is `NULL`.

**Value**

a list of model variance-covariance components determining the parameters to be estimated for the associated linear model.

**Author(s)**

Glucose

*Glucose levels over time*

---

**Description**

The `Glucose` data frame has 378 rows and 4 columns.

**Format**

This data frame contains the following columns:

**Subject** an ordered factor with levels 6 < 2 < 3 < 5 < 1 < 4

**Time** a numeric vector

**conc** a numeric vector of glucose levels

**Meal** an ordered factor with levels 2am < 6am < 10am < 2pm < 6pm < 10pm

**Source**

Hand, D. and Crowder, M. (1996), *Practical Longitudinal Data Analysis*, Chapman and Hall, London.

---

`Glucose2`*Glucose Levels Following Alcohol Ingestion*

---

**Description**

The `Glucose2` data frame has 196 rows and 4 columns.

**Format**

This data frame contains the following columns:

**Subject** a factor with levels 1 to 7 identifying the subject whose glucose level is measured.

**Date** a factor with levels 1 2 indicating the occasion in which the experiment was conducted.

**Time** a numeric vector giving the time since alcohol ingestion (in min/10).

**glucose** a numeric vector giving the blood glucose level (in mg/dl).

**Details**

Hand and Crowder (Table A.14, pp. 180-181, 1996) describe data on the blood glucose levels measured at 14 time points over 5 hours for 7 volunteers who took alcohol at time 0. The same experiment was repeated on a second date with the same subjects but with a dietary additive used for all subjects.

---

`gnls`*Fit Nonlinear Model Using Generalized Least Squares*

---

**Description**

This function fits a nonlinear model using generalized least squares. The errors are allowed to be correlated and/or have unequal variances.

**Usage**

```
gnls(model, data, params, start, correlation, weights, subset,  
      na.action, naPattern, control, verbose)
```

**Arguments**

<code>model</code>	a two-sided formula object describing the model, with the response on the left of a <code>~</code> operator and a nonlinear expression involving parameters and covariates on the right. If <code>data</code> is given, all names used in the formula should be defined as parameters or variables in the data frame.
<code>data</code>	an optional data frame containing the variables named in <code>model</code> , <code>correlation</code> , <code>weights</code> , <code>subset</code> , and <code>naPattern</code> . By default the variables are taken from the environment from which <code>gnls</code> is called.
<code>params</code>	an optional two-sided linear formula of the form $p_1 + \dots + p_n \sim x_1 + \dots + x_m$ , or list of two-sided formulas of the form $p_1 \sim x_1 + \dots + x_m$ , with possibly different models for each parameter. The $p_1, \dots, p_n$ represent parameters included on the right hand side of <code>model</code> and $x_1 + \dots + x_m$ define a linear model for the parameters (when the left hand side of the formula contains several parameters, they are all assumed to follow the same linear model described by the right hand side expression). A <code>1</code> on the right hand side of the formula(s) indicates a single fixed effects for the corresponding parameter(s). By default, the parameters are obtained from the names of <code>start</code> .
<code>start</code>	an optional named list, or numeric vector, with the initial values for the parameters in <code>model</code> . It can be omitted when a <code>selfStarting</code> function is used in <code>model</code> , in which case the starting estimates will be obtained from a single call to the <code>nls</code> function.
<code>correlation</code>	an optional <code>corStruct</code> object describing the within-group correlation structure. See the documentation of <code>corClasses</code> for a description of the available <code>corStruct</code> classes. If a grouping variable is to be used, it must be specified in the <code>form</code> argument to the <code>corStruct</code> constructor. Defaults to <code>NULL</code> , corresponding to uncorrelated errors.
<code>weights</code>	an optional <code>varFunc</code> object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to <code>varFixed</code> , corresponding to fixed variance weights. See the documentation on <code>varClasses</code> for a description of the available <code>varFunc</code> classes. Defaults to <code>NULL</code> , corresponding to homoscedastic errors.
<code>subset</code>	an optional expression indicating which subset of the rows of <code>data</code> should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
<code>na.action</code>	a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>gnls</code> to print an error message and terminate if there are any incomplete observations.
<code>naPattern</code>	an expression or formula object, specifying which returned values are to be regarded as missing.
<code>control</code>	a list of control values for the estimation algorithm to replace the default values returned by the function <code>gnlsControl</code> . Defaults to an empty list.
<code>verbose</code>	an optional logical value. If <code>TRUE</code> information on the evolution of the iterative algorithm is printed. Default is <code>FALSE</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

an object of class `gnls`, also inheriting from class `gls`, representing the nonlinear model fit. Generic functions such as `print`, `plot` and `summary` have methods to show the results of the fit. See `gnlsObject` for the components of the fit. The functions `resid`, `coef`, and `fitted` can be used to extract some of its components.

`gnlsControl`

*Control Values for gnls Fit*

---

**Description**

The values supplied in the function call replace the defaults and a list with all possible arguments is returned. The returned list is used as the `control` argument to the `gnls` function.

**Usage**

```
gnlsControl(maxIter, nlsMaxIter, msMaxIter, minScale, tolerance,
            nlsTol, msTol, msScale, returnObject, msVerbose,
            apVar, .relStep, nlmStepMax,
            opt = c("nlminb", "optim"), optimMethod,
            minAbsParApVar)
```

**Arguments**

maxIter	maximum number of iterations for the <code>gnls</code> optimization algorithm. Default is 50.
nlsMaxIter	maximum number of iterations for the <code>nls</code> optimization step inside the <code>gnls</code> optimization. Default is 7.
msMaxIter	maximum number of iterations for the <code>ms</code> optimization step inside the <code>gnls</code> optimization. Default is 50.
minScale	minimum factor by which to shrink the default step size in an attempt to decrease the sum of squares in the <code>nls</code> step. Default 0.001.
tolerance	tolerance for the convergence criterion in the <code>gnls</code> algorithm. Default is 1e-6.
nlsTol	tolerance for the convergence criterion in <code>nls</code> step. Default is 1e-3.
msTol	tolerance for the convergence criterion in <code>ms</code> , passed as the <code>rel.tolerance</code> argument to the function (see documentation on <code>ms</code> ). Default is 1e-7.
msScale	scale function passed as the <code>scale</code> argument to the <code>ms</code> function (see documentation on that function). Default is <code>lmeScale</code> .
returnObject	a logical value indicating whether the fitted object should be returned when the maximum number of iterations is reached without convergence of the algorithm. Default is <code>FALSE</code> .
msVerbose	a logical value passed as the <code>trace</code> argument to <code>ms</code> (see documentation on that function). Default is <code>FALSE</code> .
apVar	a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is <code>TRUE</code> .
.relStep	relative step for numerical derivatives calculations. Default is <code>.Machine\$double.eps^(1/3)</code> .
opt	the optimizer to be used, either <code>nlminb</code> (the default since (R 2.2.0) or <code>optim</code> (the previous default).
optimMethod	character - the optimization method to be used with the <code>optim</code> optimizer. The default is <code>"BFGS"</code> . An alternative is <code>"L-BFGS-B"</code> .
nlmStepMax	stepmax value to be passed to <code>nlm</code> . See <code>nlm</code> for details. Default is 100.0
minAbsParApVar	numeric value - minimum absolute parameter value in the approximate variance calculation. The default is 0.05.

gnlsObject

*Fitted gnls Object*

---

**Description**

An object returned by the `gnls` function, inheriting from class `gnls` and also from class `gls`, and representing a generalized nonlinear least squares fitted model. Objects of this class have methods for the generic functions `anova`, `coef`, `fitted`, `formula`, `getGroups`, `getResponse`, `intervals`, `logLik`, `plot`, `predict`, `print`, `residuals`, `summary`, and `update`.

**Value**

The following components must be included in a legitimate `gnls` object.

<code>apVar</code>	an approximate covariance matrix for the variance-covariance coefficients. If <code>apVar = FALSE</code> in the list of control values used in the call to <code>gnls</code> , this component is equal to <code>NULL</code> .
<code>call</code>	a list containing an image of the <code>gnls</code> call that produced the object.
<code>coefficients</code>	a vector with the estimated nonlinear model coefficients.
<code>contrasts</code>	a list with the contrasts used to represent factors in the model formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the model, this component will be an empty list.
<code>dims</code>	a list with basic dimensions used in the model fit, including the components <code>N</code> - the number of observations used in the fit and <code>p</code> - the number of coefficients in the nonlinear model.
<code>fitted</code>	a vector with the fitted values.
<code>modelStruct</code>	an object inheriting from class <code>gnlsStruct</code> , representing a list of model components, such as <code>corStruct</code> and <code>varFunc</code> objects.
<code>groups</code>	a vector with the correlation structure grouping factor, if any is present.
<code>logLik</code>	the log-likelihood at convergence.
<code>numIter</code>	the number of iterations used in the iterative algorithm.
<code>plist</code>	
<code>pmap</code>	
<code>residuals</code>	a vector with the residuals.
<code>sigma</code>	the estimated residual standard error.
<code>varBeta</code>	an approximate covariance matrix of the coefficients estimates.

gnlsStruct

*Generalized Nonlinear Least Squares Structure*

---

**Description**

A generalized nonlinear least squares structure is a list of model components representing different sets of parameters in the nonlinear model. A `gnlsStruct` may contain `corStruct` and `varFunc` objects. NULL arguments are not included in the `gnlsStruct` list.

**Usage**

```
gnlsStruct(corStruct, varStruct)
```

**Arguments**

`corStruct` an optional `corStruct` object, representing a correlation structure. Default is NULL.

`varStruct` an optional `varFunc` object, representing a variance function structure. Default is NULL.

**Value**

a list of model variance-covariance components determining the parameters to be estimated for the associated nonlinear model.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates  
<bates@stat.wisc.edu>

gnls1 <- gnlsStruct(corAR1(), varPower())
```

groupedData

*Construct a groupedData Object***Description**

An object of the `groupedData` class is constructed from the `formula` and `data` by attaching the `formula` as an attribute of the data, along with any of `outer`, `inner`, `labels`, and `units` that are given. If `order.groups` is `TRUE` the grouping factor is converted to an ordered factor with the ordering determined by `FUN`. Depending on the number of grouping levels and the type of primary covariate, the returned object will be of one of three classes: `nfnGroupedData` - numeric covariate, single level of nesting; `nffGroupedData` - factor covariate, single level of nesting; and `nmGroupedData` - multiple levels of nesting. Several modeling and plotting functions can use the formula stored with a `groupedData` object to construct default plots and models.

**Usage**

```
groupedData(formula, data, order.groups, FUN, outer, inner,
            labels, units)
## S3 method for class 'groupedData':
update(object, formula, data, order.groups, FUN,
       outer, inner, labels, units, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>groupedData</code> .
<code>formula</code>	a formula of the form <code>resp ~ cov   group</code> where <code>resp</code> is the response, <code>cov</code> is the primary covariate, and <code>group</code> is the grouping factor. The expression <code>1</code> can be used for the primary covariate when there is no other suitable candidate. Multiple nested grouping factors can be listed separated by the <code>/</code> symbol as in <code>fact1/fact2</code> . In an expression like this the <code>fact2</code> factor is nested within the <code>fact1</code> factor.
<code>data</code>	a data frame in which the expressions in <code>formula</code> can be evaluated. The resulting <code>groupedData</code> object will consist of the same data values in the same order but with additional attributes.
<code>order.groups</code>	an optional logical value, or list of logical values, indicating if the grouping factors should be converted to ordered factors according to the function <code>FUN</code> applied to the response from each group. If multiple levels of grouping are present, this argument can be either a single logical value (which will be repeated for all grouping levels) or a list of logical values. If no names are assigned to the list elements, they are assumed in the same order as the group levels (outermost to innermost grouping). Ordering within a level of grouping is done within the levels of the grouping factors which are outer to it. Changing the grouping factor to an ordered factor does not affect the ordering of the rows in the data frame but it does affect the order of the panels in a trellis display of the data or models fitted to the data. Defaults to <code>TRUE</code> .
<code>FUN</code>	an optional summary function that will be applied to the values of the response for each level of the grouping factor, when <code>order.groups = TRUE</code> , to determine the ordering. Defaults to the <code>max</code> function.

<code>outer</code>	an optional one-sided formula, or list of one-sided formulas, indicating covariates that are outer to the grouping factor(s). If multiple levels of grouping are present, this argument can be either a single one-sided formula, or a list of one-sided formulas. If no names are assigned to the list elements, they are assumed in the same order as the group levels (outermost to innermost grouping). An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. When plotting a groupedData object, the argument <code>outer = TRUE</code> causes the panels to be determined by the <code>outer</code> formula. The points within the panels are associated by level of the grouping factor. Defaults to <code>NULL</code> , meaning that no outer covariates are present.
<code>inner</code>	an optional one-sided formula, or list of one-sided formulas, indicating covariates that are inner to the grouping factor(s). If multiple levels of grouping are present, this argument can be either a single one-sided formula, or a list of one-sided formulas. If no names are assigned to the list elements, they are assumed in the same order as the group levels (outermost to innermost grouping). An inner covariate can change within the sets of rows defined by the grouping factor. An inner formula can be used to associate points in a plot of a groupedData object. Defaults to <code>NULL</code> , meaning that no inner covariates are present.
<code>labels</code>	an optional list of character strings giving labels for the response and the primary covariate. The label for the primary covariate is named <code>x</code> and that for the response is named <code>y</code> . Either label can be omitted.
<code>units</code>	an optional list of character strings giving the units for the response and the primary covariate. The units string for the primary covariate is named <code>x</code> and that for the response is named <code>y</code> . Either units string can be omitted.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

an object of one of the classes `nfnGroupedData`, `nffGroupedData`, or `nmGroupedData`, and also inheriting from classes `groupedData` and `data.frame`.

**Examples**

```
Orth.new <- # create a new copy of the groupedData object
  groupedData( distance ~ age | Subject,
    data = as.data.frame( Orthodont ),
    FUN = mean,
    outer = ~ Sex,
    labels = list( x = "Age",
      y = "Distance from pituitary to pterygomaxillary fissure" ),
    units = list( x = "(yr)", y = "(mm)" )

## Not run:
plot( Orth.new )          # trellis plot by Subject

## End(Not run)
formula( Orth.new )      # extractor for the formula
gsummary( Orth.new )     # apply summary by Subject
fml <- lme( Orth.new )   # fixed and groups formulae extracted from object
Orthodont2 <- update(Orthodont, FUN = mean)
```

gsummary

*Summarize by Groups***Description**

Provide a summary of the variables in a data frame by groups of rows. This is most useful with a `groupedData` object to examine the variables by group.

**Usage**

```
gsummary(object, FUN, omitGroupingFactor, form, level,
  groups, invariantsOnly, ...)
```

**Arguments**

`object` an object to be summarized - usually a `groupedData` object or a `data.frame`.

`FUN` an optional summary function or a list of summary functions to be applied to each variable in the frame. The function or functions are applied only to variables in `object` that vary within the groups defined by `groups`. Invariant variables are always summarized by group using the unique value that they assume within that group. If `FUN` is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If `FUN` is a list of functions, the names in the list should designate classes of variables in the frame such as `ordered`, `factor`, or `numeric`. The indicated function will be applied to any non-invariant variables of that class. The default functions to be used are `mean` for numeric factors, and `Mode` for both `factor` and `ordered`. The `Mode` function, defined internally in `gsummary`, returns the modal or most popular value of the variable. It is different from the `mode` function that returns the S-language mode of the variable.

`omitGroupingFactor` an optional logical value. When `TRUE` the grouping factor itself will be omitted from the group-wise summary but the levels of the grouping factor will continue to be used as the row names for the data frame that is produced by the summary. Defaults to `FALSE`.

form	an optional one-sided formula that defines the groups. When this formula is given, the right-hand side is evaluated in <code>object</code> , converted to a factor if necessary, and the unique levels are used to define the groups. Defaults to <code>formula(object)</code> .
level	an optional positive integer giving the level of grouping to be used in an object with multiple nested grouping levels. Defaults to the highest or innermost level of grouping.
groups	an optional factor that will be used to split the rows into groups. Defaults to <code>getGroups(object, form, level)</code> .
invariantsOnly	an optional logical value. When <code>TRUE</code> only those covariates that are invariant within each group will be summarized. The summary value for the group is always the unique value taken on by that covariate within the group. The columns in the summary are of the same class as the corresponding columns in <code>object</code> . By definition, the grouping factor itself must be an invariant. When combined with <code>omitGroupingFactor = TRUE</code> , this option can be used to discover if there are invariant covariates in the data frame. Defaults to <code>FALSE</code> .
...	optional additional arguments to the summary functions that are invoked on the variables by group. Often it is helpful to specify <code>na.rm = TRUE</code> .

### Value

A `data.frame` with one row for each level of the grouping factor. The number of columns is at most the number of columns in `object`.

### Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

### Examples

```
gsummary(Orthodont) # default summary by Subject
## gsummary with invariantsOnly = TRUE and omitGroupingFactor = TRUE
## determines whether there are covariates like Sex that are invariant
## within the repeated observations on the same Subject.
gsummary(Orthodont, inv = TRUE, omit = TRUE)
```

---

 Gun

*Methods for firing naval guns*

---

### Description

The Gun data frame has 36 rows and 4 columns.

### Format

This data frame contains the following columns:

**rounds** a numeric vector

**Method** a factor with levels M1 M2

**Team** an ordered factor with levels T1S < T3S < T2S < T1A < T2A < T3A < T1H < T3H < T2H

**Physique** an ordered factor with levels Slight < Average < Heavy

### Details

Hicks (p.180, 1993) reports data from an experiment on methods for firing naval guns. Gunners of three different physiques (slight, average, and heavy) tested two firing methods. Both methods were tested twice by each of nine teams of three gunners with identical physique. The response was the number of rounds fired per minute.

---

 IGF

*Radioimmunoassay of IGF-I Protein*

---

### Description

The IGF data frame has 237 rows and 3 columns.

### Format

This data frame contains the following columns:

**Lot** an ordered factor giving the radioactive tracer lot.

**age** a numeric vector giving the age (in days) of the radioactive tracer.

**conc** a numeric vector giving the estimated concentration of IGF-I protein (ng/ml)

### Details

Davidian and Giltinan (1995) describe data obtained during quality control radioimmunoassays for ten different lots of radioactive tracer used to calibrate the Insulin-like Growth Factor (IGF-I) protein concentration measurements.

`Initialize`*Initialize Object*

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `corStruct`, `lmeStruct`, `reStruct`, and `varFunc`.

**Usage**

```
Initialize(object, data, ...)
```

**Arguments**

<code>object</code>	any object requiring initialization, e.g. "plug-in" structures such as <code>corStruct</code> and <code>varFunc</code> objects.
<code>data</code>	a data frame to be used in the initialization procedure.
<code>...</code>	some methods for this generic function require additional arguments.

**Value**

an initialized object with the same class as `object`. Changes introduced by the initialization procedure will depend on the method function used; see the appropriate documentation.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**References**

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

```

`Initialize.corStruct`*Initialize corStruct Object*

---

### Description

This method initializes `object` by evaluating its associated covariate(s) and grouping factor, if any is present, in `data`, calculating various dimensions and constants used by optimization algorithms involving `corStruct` objects (see the appropriate `Dim` method documentation), and assigning initial values for the coefficients in `object`, if none were present.

### Usage

```
## S3 method for class 'corStruct':  
Initialize(object, data, ...)
```

### Arguments

<code>object</code>	an object inheriting from class <code>corStruct</code> representing a correlation structure.
<code>data</code>	a data frame in which to evaluate the variables defined in <code>formula(object)</code> .
<code>...</code>	this argument is included to make this method compatible with the generic.

### Value

an initialized object with the same class as `object` representing a correlation structure.

### Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates  
<bates@stat.wisc.edu>

### References

### Examples

```
cs1 <- corAR1(form = ~ 1 | Subject)  
cs1 <- Initialize(cs1, data = Orthodont)
```

---

`Initialize.glsStruct`*Initialize a glsStruct Object*

---

**Description**

The individual linear model components of the `glsStruct` list are initialized.

**Usage**

```
## S3 method for class 'glsStruct':  
Initialize(object, data, control, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>glsStruct</code> , representing a list of linear model components, such as <code>corStruct</code> and <code>varFunc</code> objects.
<code>data</code>	a data frame in which to evaluate the variables defined in <code>formula(object)</code> .
<code>control</code>	an optional list with control parameters for the initialization and optimization algorithms used in <code>gls</code> . Defaults to <code>list(singular.ok = FALSE, qrTol = .Machine\$single.eps)</code> , implying that linear dependencies are not allowed in the model and that the tolerance for detecting linear dependencies among the columns of the regression matrix is <code>.Machine\$single.eps</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a `glsStruct` object similar to `object`, but with initialized model components.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

---

`Initialize.lmeStruct`*Initialize an lmeStruct Object*

---

**Description**

The individual linear mixed-effects model components of the `lmeStruct` list are initialized.

**Usage**

```
## S3 method for class 'lmeStruct':
Initialize(object, data, groups, conLin, control, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>lmeStruct</code> , representing a list of linear mixed-effects model components, such as <code>reStruct</code> , <code>corStruct</code> , and <code>varFunc</code> objects.
<code>data</code>	a data frame in which to evaluate the variables defined in <code>formula(object)</code> .
<code>groups</code>	a data frame with the grouping factors corresponding to the lme model associated with <code>object</code> as columns, sorted from innermost to outermost grouping level.
<code>conLin</code>	an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying lme model. Defaults to <code>attr(object, "conLin")</code> .
<code>control</code>	an optional list with control parameters for the initialization and optimization algorithms used in lme. Defaults to <code>list(niterEM=20, gradHess=TRUE)</code> , implying that 20 EM iterations are to be used in the derivation of initial estimates for the coefficients of the <code>reStruct</code> component of <code>object</code> and, if possible, numerical gradient vectors and Hessian matrices for the log-likelihood function are to be used in the optimization algorithm.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

an `lmeStruct` object similar to `object`, but with initialized model components.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

---

Initialize.reStruct

*Initialize reStruct Object*

---

**Description**

Initial estimates for the parameters in the `pdMat` objects forming `object`, which have not yet been initialized, are obtained using the methodology described in Bates and Pinheiro (1998). These estimates may be refined using a series of EM iterations, as described in Bates and Pinheiro (1998). The number of EM iterations to be used is defined in `control`.

**Usage**

```
## S3 method for class 'reStruct':
Initialize(object, data, conLin, control, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>reStruct</code> , representing a random effects structure and consisting of a list of <code>pdMat</code> objects.
<code>data</code>	a data frame in which to evaluate the variables defined in <code>formula(object)</code> .
<code>conLin</code>	a condensed linear model object, consisting of a list with components <code>"Xy"</code> , corresponding to a regression matrix ( $X$ ) combined with a response vector ( $y$ ), and <code>"logLik"</code> , corresponding to the log-likelihood of the underlying model.
<code>control</code>	an optional list with a single component <code>niterEM</code> controlling the number of iterations for the EM algorithm used to refine initial parameter estimates. It is given as a list for compatibility with other <code>Initialize</code> methods. Defaults to <code>list(niterEM = 20)</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

an `reStruct` object similar to `object`, but with all `pdMat` components initialized.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[reStruct](#), [pdMat](#), [Initialize](#)

---

Initialize.varFunc *Initialize varFunc Object*

---

**Description**

This method initializes `object` by evaluating its associated covariate(s) and grouping factor, if any is present, in `data`; determining if the covariate(s) need to be updated when the values of the coefficients associated with `object` change; initializing the log-likelihood and the weights associated with `object`; and assigning initial values for the coefficients in `object`, if none were present. The covariate(s) will only be initialized if no update is needed when `coef(object)` changes.

**Usage**

```
## S3 method for class 'varFunc':
Initialize(object, data, ...)
```

**Arguments**

`object` an object inheriting from class `varFunc`, representing a variance function structure.

`data` a data frame in which to evaluate the variables named in `formula(object)`.

`...` this argument is included to make this method compatible with the generic.

**Value**

an initialized object with the same class as `object` representing a variance function structure.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[Initialize](#)

**Examples**

```
vf1 <- varPower( form = ~ age | Sex )
vf1 <- Initialize( vf1, Orthodont )
```

---

intervals

*Confidence Intervals on Coefficients*

---

**Description**

Confidence intervals on the parameters associated with the model represented by `object` are obtained. This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `gls`, `lme`, and `lmList`.

**Usage**

```
intervals(object, level, ...)
```

**Arguments**

`object` a fitted model object from which parameter estimates can be extracted.

`level` an optional numeric value for the interval confidence level. Defaults to 0.95.

`...` some methods for the generic may require additional arguments.

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**References**

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

**Examples**

```
## see the method documentation
```

---

```
intervals.gls
```

*Confidence Intervals on gls Parameters*

---

**Description**

Approximate confidence intervals for the parameters in the linear model represented by `object` are obtained, using a normal approximation to the distribution of the (restricted) maximum likelihood estimators (the estimators are assumed to have a normal distribution centered at the true parameter values and with covariance matrix equal to the negative inverse Hessian matrix of the (restricted) log-likelihood evaluated at the estimated parameters). Confidence intervals are obtained in an unconstrained scale first, using the normal approximation, and, if necessary, transformed to the constrained scale.

**Usage**

```
## S3 method for class 'gls':
intervals(object, level, which, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>gls</code> , representing a generalized least squares fitted linear model.
<code>level</code>	an optional numeric value for the interval confidence level. Defaults to 0.95.
<code>which</code>	an optional character string specifying the subset of parameters for which to construct the confidence intervals. Possible values are "all" for all parameters, "var-cov" for the variance-covariance parameters only, and "coef" for the linear model coefficients only. Defaults to "all".
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a list with components given by data frames with rows corresponding to parameters and columns `lower`, `est`, and `upper` representing respectively lower confidence limits, the estimated values, and upper confidence limits for the parameters. Possible components are:

<code>coef</code>	linear model coefficients, only present when <code>which</code> is not equal to "var-cov".
<code>corStruct</code>	correlation parameters, only present when <code>which</code> is not equal to "coef" and a correlation structure is used in <code>object</code> .

varFunc        variance function parameters, only present when which is not equal to "coef" and a variance function structure is used in object.

sigma         residual standard error.

intervals(fml)
```

---

intervals.lme

*Confidence Intervals on lme Parameters*

---

**Description**

Approximate confidence intervals for the parameters in the linear mixed-effects model represented by `object` are obtained, using a normal approximation to the distribution of the (restricted) maximum likelihood estimators (the estimators are assumed to have a normal distribution centered at the true parameter values and with covariance matrix equal to the negative inverse Hessian matrix of the (restricted) log-likelihood evaluated at the estimated parameters). Confidence intervals are obtained in an unconstrained scale first, using the normal approximation, and, if necessary, transformed to the constrained scale. The `pdNatural` parametrization is used for general positive-definite matrices.

**Usage**

```
## S3 method for class 'lme':
intervals(object, level, which, ...)
```

**Arguments**

`object`        an object inheriting from class `lme`, representing a fitted linear mixed-effects model.

`level`         an optional numeric value with the confidence level for the intervals. Defaults to 0.95.

`which`         an optional character string specifying the subset of parameters for which to construct the confidence intervals. Possible values are "all" for all parameters, "var-cov" for the variance-covariance parameters only, and "fixed" for the fixed effects only. Defaults to "all".

`...`         some methods for this generic require additional arguments. None are used in this method.

**Value**

a list with components given by data frames with rows corresponding to parameters and columns `lower`, `est.`, and `upper` representing respectively lower confidence limits, the estimated values, and upper confidence limits for the parameters. Possible components are:

<code>fixed</code>	fixed effects, only present when <code>which</code> is not equal to <code>"var-cov"</code> .
<code>reStruct</code>	random effects variance-covariance parameters, only present when <code>which</code> is not equal to <code>"fixed"</code> .
<code>corStruct</code>	within-group correlation parameters, only present when <code>which</code> is not equal to <code>"fixed"</code> and a correlation structure is used in <code>object</code> .
<code>varFunc</code>	within-group variance function parameters, only present when <code>which</code> is not equal to <code>"fixed"</code> and a variance function structure is used in <code>object</code> .
<code>sigma</code>	within-group standard deviation.

```

---

`intervals.lmList`     *Confidence Intervals on lmList Coefficients*

---

**Description**

Confidence intervals on the linear model coefficients are obtained for each `lm` component of `object` and organized into a three dimensional array. The first dimension corresponding to the names of the `object` components. The second dimension is given by `lower`, `est.`, and `upper` corresponding, respectively, to the lower confidence limit, estimated coefficient, and upper confidence limit. The third dimension is given by the coefficients names.

**Usage**

```
## S3 method for class 'lmList':
intervals(object, level, pool, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>lmList</code> , representing a list of <code>lm</code> objects with a common model.
<code>level</code>	an optional numeric value with the confidence level for the intervals. Defaults to 0.95.
<code>pool</code>	an optional logical value indicating whether a pooled estimate of the residual standard error should be used. Default is <code>attr(object, "pool")</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a three dimensional array with the confidence intervals and estimates for the coefficients of each `lm` component of `object`.

fml <- lmList(distance ~ age | Subject, Orthodont)
intervals(fml)
```

---

isBalanced

*Check a Design for Balance*

---

**Description**

Check the design of the experiment or study for balance.

**Usage**

```
isBalanced(object, countOnly, level)
```

**Arguments**

object	A <code>groupedData</code> object containing a data frame and a formula that describes the roles of variables in the data frame. The object will have one or more nested grouping factors and a primary covariate.
countOnly	A logical value indicating if the check for balance should only consider the number of observations at each level of the grouping factor(s). Defaults to <code>FALSE</code> .
level	an optional integer vector specifying the desired prediction levels. Levels increase from outermost to innermost grouping, with level 0 representing the population (fixed effects) predictions. Defaults to the innermost level.

**Details**

A design is balanced with respect to the grouping factor(s) if there are the same number of observations at each distinct value of the grouping factor or each combination of distinct levels of the nested grouping factors. If `countOnly` is `FALSE` the design is also checked for balance with respect to the primary covariate, which is often the time of the observation. A design is balanced with respect to the grouping factor and the covariate if the number of observations at each distinct level (or combination of levels for nested factors) is constant and the times at which the observations are taken (in general, the values of the primary covariates) also are constant.

**Value**

`TRUE` or `FALSE` according to whether the data are balanced or not

**Author(s)**

isBalanced(Pixel, level = 1)    # should return FALSE
```

---

isInitialized      *Check if Object is Initialized*

---

**Description**

Checks if `object` has been initialized (generally through a call to `Initialize`), by searching for components and attributes which are modified during initialization.

**Usage**

```
isInitialized(object)
```

**Arguments**

`object` any object requiring initialization.

**Value**

a logical value indicating whether `object` has been initialized.

**Author(s)**

Jose Pinheiro and Douglas Bates

**See Also**

**Examples**

```
pd1 <- pdDiag(~age)
isInitialized(pd1)
```

---

LDEsysMat

*Generate system matrix for LDEs*

---

**Description**

Generate the system matrix for the linear differential equations determined by a compartment model.

**Usage**

```
LDEsysMat(pars, incidence)
```

**Arguments**

`pars` a numeric vector of parameter values.

`incidence` an integer matrix with columns named `From`, `To`, and `Par`. Values in the `Par` column must be in the range 1 to `length(pars)`. Values in the `From` column must be between 1 and the number of compartments. Values in the `To` column must be between 0 and the number of compartments.

**Details**

A compartment model describes material transfer between  $k$  in a system of  $k$  compartments to a linear system of differential equations. Given a description of the system and a vector of parameter values this function returns the system matrix.

This function is intended for use in a general system for solving compartment models, as described in Bates and Watts (1988).

**Value**

A  $k$  by  $k$  numeric matrix.

lme

*Linear Mixed-Effects Models*

---

**Description**

This generic function fits a linear mixed-effects model in the formulation described in Laird and Ware (1982) but allowing for nested random effects. The within-group errors are allowed to be correlated and/or have unequal variances.

**Usage**

```
lme(fixed, data, random, correlation, weights, subset, method,
    na.action, control, contrasts = NULL, keep.data = TRUE)
## S3 method for class 'lme':
update(object, fixed., ..., evaluate = TRUE)
```

**Arguments**

object	an object inheriting from class <code>lme</code> , representing a fitted linear mixed-effects model.
fixed	a two-sided linear formula object describing the fixed-effects part of the model, with the response on the left of a <code>~</code> operator and the terms, separated by <code>+</code> operators, on the right, an <code>lmList</code> object, or a <code>groupedData</code> object. The method functions <code>lme.lmList</code> and <code>lme.groupedData</code> are documented separately.
fixed.	Changes to the fixed-effects formula – see <code>update.formula</code> for details.
data	an optional data frame containing the variables named in <code>fixed</code> , <code>random</code> , <code>correlation</code> , <code>weights</code> , and <code>subset</code> . By default the variables are taken from the environment from which <code>lme</code> is called.
random	optionally, any of the following: (i) a one-sided formula of the form <code>~x1+...+xn   g1/.../gm</code> , with <code>x1+...+xn</code> specifying the model for the random effects and <code>g1/.../gm</code> the grouping structure ( <code>m</code> may be equal to 1, in which case no <code>/</code> is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a list

of one-sided formulas of the form  $\sim x_1 + \dots + x_n \mid g$ , with possibly different random effects models for each grouping level. The order of nesting will be assumed the same as the order of the elements in the list; (iii) a one-sided formula of the form  $\sim x_1 + \dots + x_n$ , or a `pdMat` object with a formula (i.e. a non-NULL value for `formula(object)`), or a list of such formulas or `pdMat` objects. In this case, the grouping structure formula will be derived from the data used to fit the linear mixed-effects model, which should inherit from class `groupedData`; (iv) a named list of formulas or `pdMat` objects as in (iii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the elements in the list; (v) an `reStruct` object. See the documentation on `pdClasses` for a description of the available `pdMat` classes. Defaults to a formula consisting of the right hand side of `fixed`.

<code>correlation</code>	an optional <code>corStruct</code> object describing the within-group correlation structure. See the documentation of <code>corClasses</code> for a description of the available <code>corStruct</code> classes. Defaults to <code>NULL</code> , corresponding to no within-group correlations.
<code>weights</code>	an optional <code>varFunc</code> object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to <code>varFixed</code> , corresponding to fixed variance weights. See the documentation on <code>varClasses</code> for a description of the available <code>varFunc</code> classes. Defaults to <code>NULL</code> , corresponding to homoscedastic within-group errors.
<code>subset</code>	an optional expression indicating the subset of the rows of <code>data</code> that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
<code>method</code>	a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "REML".
<code>na.action</code>	a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>lme</code> to print an error message and terminate if there are any incomplete observations.
<code>control</code>	a list of control values for the estimation algorithm to replace the default values returned by the function <code>lmeControl</code> . Defaults to an empty list.
<code>contrasts</code>	an optional list. See the <code>contrasts.arg</code> of <code>model.matrix.default</code> .
<code>keep.data</code>	logical: should the <code>data</code> argument (if supplied and a data frame) be saved as part of the model object?
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.
<code>evaluate</code>	If <code>TRUE</code> evaluate the new call else return the call.

**Value**

an object of class `lme` representing the linear mixed-effects model fit. Generic functions such as `print`, `plot` and `summary` have methods to show the results of the fit. See `lmeObject` for the components of the fit. The functions `resid`, `coef`, `fitted`, `fixed.effects`, and `random.effects` can be used to extract some of its components.

summary(fm1)
summary(fm2)
```

---

`lme.groupedData`      *LME fit from groupedData Object*

---

## Description

The response variable and primary covariate in `formula` (`fixed`) are used to construct the fixed effects model formula. This formula and the `groupedData` object are passed as the `fixed` and `data` arguments to `lme.formula`, together with any other additional arguments in the function call. See the documentation on `lme.formula` for a description of that function.

**Usage**

```
## S3 method for class 'groupedData':
lme(fixed, data, random, correlation, weights,
    subset, method, na.action, control, contrasts, keep.data = TRUE)
```

**Arguments**

<code>fixed</code>	a data frame inheriting from class <code>groupedData</code> .
<code>data</code>	this argument is included for consistency with the generic function. It is ignored in this method function.
<code>random</code>	optionally, any of the following: (i) a one-sided formula of the form $\sim x_1 + \dots + x_n \mid g_1 / \dots / g_m$ , with $x_1 + \dots + x_n$ specifying the model for the random effects and $g_1 / \dots / g_m$ the grouping structure ( $m$ may be equal to 1, in which case no $/$ is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a list of one-sided formulas of the form $\sim x_1 + \dots + x_n \mid g$ , with possibly different random effects models for each grouping level. The order of nesting will be assumed the same as the order of the elements in the list; (iii) a one-sided formula of the form $\sim x_1 + \dots + x_n$ , or a <code>pdMat</code> object with a formula (i.e. a non-NULL value for <code>formula(object)</code> ), or a list of such formulas or <code>pdMat</code> objects. In this case, the grouping structure formula will be derived from the data used to fit the linear mixed-effects model, which should inherit from class <code>groupedData</code> ; (iv) a named list of formulas or <code>pdMat</code> objects as in (iii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the order of the elements in the list; (v) an <code>reStruct</code> object. See the documentation on <code>pdClasses</code> for a description of the available <code>pdMat</code> classes. Defaults to a formula consisting of the right hand side of <code>fixed</code> .
<code>correlation</code>	an optional <code>corStruct</code> object describing the within-group correlation structure. See the documentation of <code>corClasses</code> for a description of the available <code>corStruct</code> classes. Defaults to <code>NULL</code> , corresponding to no within-group correlations.
<code>weights</code>	an optional <code>varFunc</code> object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to <code>varFixed</code> , corresponding to fixed variance weights. See the documentation on <code>varClasses</code> for a description of the available <code>varFunc</code> classes. Defaults to <code>NULL</code> , corresponding to homoscedastic within-group errors.
<code>subset</code>	an optional expression indicating the subset of the rows of <code>data</code> that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
<code>method</code>	a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "REML".
<code>na.action</code>	a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>lme</code> to print an error message and terminate if there are any incomplete observations.
<code>control</code>	a list of control values for the estimation algorithm to replace the default values returned by the function <code>lmeControl</code> . Defaults to an empty list.
<code>contrasts</code>	an optional list. See the <code>contrasts.arg</code> of <code>model.matrix.default</code> .
<code>keep.data</code>	logical: should the <code>data</code> argument (if supplied and a data frame) be saved as part of the model object?

**Value**

an object of class `lme` representing the linear mixed-effects model fit. Generic functions such as `print`, `plot` and `summary` have methods to show the results of the fit. See `lmeObject` for the components of the fit. The functions `resid`, `coef`, `fitted`, `fixed.effects`, and `random.effects` can be used to extract some of its components.

lme.lmList

*LME fit from lmList Object***Description**

If the random effects names defined in `random` are a subset of the `lmList` object coefficient names, initial estimates for the covariance matrix of the random effects are obtained (overwriting any values given in `random`). `formula(fixed)` and the `data` argument in the calling sequence used to obtain `fixed` are passed as the `fixed` and `data` arguments to `lme.formula`, together with any other additional arguments in the function call. See the documentation on `lme.formula` for a description of that function.

**Usage**

```
## S3 method for class 'lmList':
lme(fixed, data, random, correlation, weights, subset, method,
    na.action, control, contrasts, keep.data)
```

**Arguments**

<code>fixed</code>	an object inheriting from class <code>lmList</code> , representing a list of <code>lm</code> fits with a common model.
<code>data</code>	this argument is included for consistency with the generic function. It is ignored in this method function.
<code>random</code>	an optional one-sided linear formula with no conditioning expression, or a <code>pdMat</code> object with a <code>formula</code> attribute. Multiple levels of grouping are not allowed with this method function. Defaults to a formula consisting of the right hand side of <code>formula(fixed)</code> .
<code>correlation</code>	an optional <code>corStruct</code> object describing the within-group correlation structure. See the documentation of <code>corClasses</code> for a description of the available <code>corStruct</code> classes. Defaults to <code>NULL</code> , corresponding to no within-group correlations.
<code>weights</code>	an optional <code>varFunc</code> object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to <code>varFixed</code> , corresponding to fixed variance weights. See the documentation on <code>varClasses</code> for a description of the available <code>varFunc</code> classes. Defaults to <code>NULL</code> , corresponding to homoscedastic within-group errors.
<code>subset</code>	an optional expression indicating the subset of the rows of <code>data</code> that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
<code>method</code>	a character string. If <code>"REML"</code> the model is fit by maximizing the restricted log-likelihood. If <code>"ML"</code> the log-likelihood is maximized. Defaults to <code>"REML"</code> .
<code>na.action</code>	a function that indicates what should happen when the data contain <code>NA</code> s. The default action ( <code>na.fail</code> ) causes <code>lme</code> to print an error message and terminate if there are any incomplete observations.
<code>control</code>	a list of control values for the estimation algorithm to replace the default values returned by the function <code>lmeControl</code> . Defaults to an empty list.

`contrasts` an optional list. See the `contrasts.arg` of `model.matrix.default`.  
`keep.data` logical: should the data argument (if supplied and a data frame) be saved as part of the model object?

### Value

an object of class `lme` representing the linear mixed-effects model fit. Generic functions such as `print`, `plot` and `summary` have methods to show the results of the fit. See `lmeObject` for the components of the fit. The functions `resid`, `coef`, `fitted`, `fixed.effects`, and `random.effects` can be used to extract some of its components.

---

lmeControl

*Control Values for lme Fit*

---

### Description

The values supplied in the function call replace the defaults and a list with all possible arguments is returned. The returned list is used as the `control` argument to the `lme` function.

### Usage

```
lmeControl(maxIter, msMaxIter, tolerance, niterEM, msMaxEval, msTol,
           msScale, msVerbose, returnObject, gradHess, apVar,
           .relStep, minAbsParApVar, nlmStepMax,
           opt = c("nlminb", "optim"), optimMethod,
           natural)
```

### Arguments

<code>maxIter</code>	maximum number of iterations for the <code>lme</code> optimization algorithm. Default is 50.
<code>msMaxIter</code>	maximum number of iterations for the <code>nlm</code> optimization step inside the <code>lme</code> optimization. Default is 50.
<code>tolerance</code>	tolerance for the convergence criterion in the <code>lme</code> algorithm. Default is 1e-6.
<code>niterEM</code>	number of iterations for the EM algorithm used to refine the initial estimates of the random effects variance-covariance coefficients. Default is 25.
<code>msMaxEval</code>	maximum number of evaluations of the objective function permitted for <code>nlminb</code> . Default is 200.
<code>msTol</code>	tolerance for the convergence criterion in <code>nlm</code> , passed as the <code>rel.tolerance</code> argument to the function (see documentation on <code>nlm</code> ). Default is 1e-7.
<code>msScale</code>	scale function passed as the <code>scale</code> argument to the <code>nlm</code> function (see documentation on that function). Default is <code>lmeScale</code> .
<code>msVerbose</code>	a logical value passed as the <code>trace</code> argument to <code>nlm</code> (see documentation on that function). Default is <code>FALSE</code> .
<code>returnObject</code>	a logical value indicating whether the fitted object should be returned when the maximum number of iterations is reached without convergence of the algorithm. Default is <code>FALSE</code> .
<code>gradHess</code>	a logical value indicating whether numerical gradient vectors and Hessian matrices of the log-likelihood function should be used in the <code>nlm</code> optimization. This option is only available when the correlation structure ( <code>corStruct</code> ) and the variance function structure ( <code>varFunc</code> ) have no "varying" parameters and the <code>pdMat</code> classes used in the random effects structure are <code>pdSymm</code> (general positive-definite), <code>pdDiag</code> (diagonal), <code>pdIdent</code> (multiple of the identity), or <code>pdCompSymm</code> (compound symmetry). Default is <code>TRUE</code> .
<code>apVar</code>	a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is <code>TRUE</code> .
<code>.relStep</code>	relative step for numerical derivatives calculations. Default is <code>.Machine\$double.eps^(1/3)</code> .

nlmStepMax	stepmax value to be passed to nlm. See <a href="#">nlm</a> for details. Default is 100.0
opt	the optimizer to be used, either <a href="#">nlminb</a> (the default since (R 2.2.0) or <a href="#">optim</a> (the previous default).
optimMethod	character - the optimization method to be used with the <a href="#">optim</a> optimizer. The default is "BFGS". An alternative is "L-BFGS-B".
minAbsParApVar	numeric value - minimum absolute parameter value in the approximate variance calculation. The default is 0.05.
natural	a logical value indicating whether the <code>pdNatural</code> parametrization should be used for general positive-definite matrices ( <code>pdSymm</code> ) in <code>reStruct</code> , when the approximate covariance matrix of the estimators is calculated. Default is <code>TRUE</code> .

**Value**

a list with components for each of the possible arguments.

```

---

lmeObject

*Fitted lme Object*

---

**Description**

An object returned by the `lme` function, inheriting from class `lme` and representing a fitted linear mixed-effects model. Objects of this class have methods for the generic functions `anova`, `coef`, `fitted`, `fixed.effects`, `formula`, `getGroups`, `getResponse`, `intervals`, `logLik`, `pairs`, `plot`, `predict`, `print`, `random.effects`, `residuals`, `summary`, and `update`.

**Value**

The following components must be included in a legitimate `lme` object.

apVar	an approximate covariance matrix for the variance-covariance coefficients. If <code>apVar = FALSE</code> in the list of control values used in the call to <code>lme</code> , this component is equal to <code>NULL</code> .
call	a list containing an image of the <code>lme</code> call that produced the object.

<code>coefficients</code>	a list with two components, <code>fixed</code> and <code>random</code> , where the first is a vector containing the estimated fixed effects and the second is a list of matrices with the estimated random effects for each level of grouping. For each matrix in the <code>random</code> list, the columns refer to the random effects and the rows to the groups.
<code>contrasts</code>	a list with the contrasts used to represent factors in the fixed effects formula and/or random effects formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the lme model, this component will be an empty list.
<code>dims</code>	a list with basic dimensions used in the lme fit, including the components <code>N</code> - the number of observations in the data, <code>Q</code> - the number of grouping levels, <code>qvec</code> - the number of random effects at each level from innermost to outermost (last two values are equal to zero and correspond to the fixed effects and the response), <code>ngrps</code> - the number of groups at each level from innermost to outermost (last two values are one and correspond to the fixed effects and the response), and <code>ncol</code> - the number of columns in the model matrix for each level of grouping from innermost to outermost (last two values are equal to the number of fixed effects and one).
<code>fitted</code>	a data frame with the fitted values as columns. The leftmost column corresponds to the population fixed effects (corresponding to the fixed effects only) and successive columns from left to right correspond to increasing levels of grouping.
<code>fixDF</code>	a list with components <code>X</code> and <code>terms</code> specifying the denominator degrees of freedom for, respectively, t-tests for the individual fixed effects and F-tests for the fixed-effects terms in the models.
<code>groups</code>	a data frame with the grouping factors as columns. The grouping level increases from left to right.
<code>logLik</code>	the (restricted) log-likelihood at convergence.
<code>method</code>	the estimation method: either "ML" for maximum likelihood, or "REML" for restricted maximum likelihood.
<code>modelStruct</code>	an object inheriting from class <code>lmeStruct</code> , representing a list of mixed-effects model components, such as <code>reStruct</code> , <code>corStruct</code> , and <code>varFunc</code> objects.
<code>numIter</code>	the number of iterations used in the iterative algorithm.
<code>residuals</code>	a data frame with the residuals as columns. The leftmost column corresponds to the population residuals and successive columns from left to right correspond to increasing levels of grouping.
<code>sigma</code>	the estimated within-group error standard deviation.
<code>varFix</code>	an approximate covariance matrix of the fixed effects estimates.

---

`lmeScale`*Scale for lme Optimization*

---

**Description**

This function calculates the scales to be used for each coefficient estimated through an `nlm` optimization in the `lme` function. If all initial values are zero, the scale is set to one for all coefficients; else, the scale for a coefficient with non-zero initial value is equal to the inverse of its initial value and the scale for the coefficients with initial value equal to zero is set to the median of the non-zero initial value coefficients.

**Usage**

```
lmeScale(start)
```

**Arguments**

`start`            the starting values for the coefficients to be estimated.

**Value**

a vector with the scales to be used in `nlm` for estimating the coefficients.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates  
<bates@stat.wisc.edu>

---

`lmeStruct`*Linear Mixed-Effects Structure*

---

**Description**

A linear mixed-effects structure is a list of model components representing different sets of parameters in the linear mixed-effects model. An `lmeStruct` list must contain at least a `reStruct` object, but may also contain `corStruct` and `varFunc` objects. `NULL` arguments are not included in the `lmeStruct` list.

**Usage**

```
lmeStruct(reStruct, corStruct, varStruct)
```

**Arguments**

reStruct	a reStruct representing a random effects structure.
corStruct	an optional corStruct object, representing a correlation structure. Default is NULL.
varStruct	an optional varFunc object, representing a variance function structure. Default is NULL.

**Value**

a list of model components determining the parameters to be estimated for the associated linear mixed-effects model.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

**Examples**

```
lms1 <- lmeStruct(reStruct(~age), corAR1(), varPower())
```

---

lmList

---

*List of lm Objects with a Common Model*

---

**Description**

Data is partitioned according to the levels of the grouping factor `g` and individual `lm` fits are obtained for each data partition, using the model defined in `object`.

**Usage**

```
lmList(object, data, level, subset, na.action, pool)
## S3 method for class 'lmList':
update(object, formula., ..., evaluate = TRUE)
## S3 method for class 'lmList':
print(x, pool, ...)
```

**Arguments**

`object` For `lmList`, either a linear formula object of the form `y ~ x1+...+xn | g` or a `groupedData` object. In the formula object, `y` represents the response, `x1, ..., xn` the covariates, and `g` the grouping factor specifying the partitioning of the data according to which different `lm` fits should be performed. The grouping factor `g` may be omitted from the formula, in which case the grouping structure will be obtained from `data`, which must inherit from class `groupedData`. The method function `lmList.groupedData` is documented separately. For the method `update.lmList`, `object` is an object inheriting from class `lmList`.

<code>formula</code>	(used in <code>update.lmList</code> only) a two-sided linear formula with the common model for the individuals <code>lm</code> fits.
<code>formula.</code>	Changes to the formula – see <code>update.formula</code> for details.
<code>data</code>	a data frame in which to interpret the variables named in <code>object</code> .
<code>level</code>	an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.
<code>subset</code>	an optional expression indicating which subset of the rows of <code>data</code> should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
<code>na.action</code>	a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>lmList</code> to print an error message and terminate if there are any incomplete observations.
<code>pool</code>	an optional logical value indicating whether a pooled estimate of the residual standard error should be used in calculations of standard deviations or standard errors for summaries.
<code>x</code>	an object inheriting from class <code>lmList</code> to be printed.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.
<code>evaluate</code>	If <code>TRUE</code> evaluate the new call else return the call.

### Value

a list of `lm` objects with as many components as the number of groups defined by the grouping factor. Generic functions such as `coef`, `fixed.effects`, `lme`, `pairs`, `plot`, `predict`, `random.effects`, `summary`, and `update` have methods that can be applied to an `lmList` object.

### References

### Examples

```
fml <- lmList(distance ~ age | Subject, Orthodont)
summary(fml)
```

---

lmList.groupedData *lmList Fit from a groupedData Object*

---

### Description

The response variable and primary covariate in `formula(object)` are used to construct the linear model formula. This formula and the `groupedData` object are passed as the `object` and `data` arguments to `lmList.formula`, together with any other additional arguments in the function call. See the documentation on `lmList.formula` for a description of that function.

### Usage

```
## S3 method for class 'groupedData':
lmList(object, data, level, subset, na.action, pool)
```

### Arguments

<code>object</code>	a data frame inheriting from class <code>groupedData</code> .
<code>data</code>	this argument is included for consistency with the generic function. It is ignored in this method function.
<code>level</code>	an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.
<code>subset</code>	an optional expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
<code>na.action</code>	a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>lmList</code> to print an error message and terminate if there are any incomplete observations.
<code>pool</code>	an optional logical value that is preserved as an attribute of the returned value. This will be used as the default for <code>pool</code> in calculations of standard deviations or standard errors for summaries.

### Value

a list of `lm` objects with as many components as the number of groups defined by the grouping factor. Generic functions such as `coef`, `fixed.effects`, `lme`, `pairs`, `plot`, `predict`, `random.effects`, `summary`, and `update` have methods that can be applied to an `lmList` object.

logDet

---

*Extract the Logarithm of the Determinant*

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `corStruct`, several `pdMat` classes, and `reStruct`.

**Usage**

```
logDet(object, ...)
```

**Arguments**

<code>object</code>	any object from which a matrix, or list of matrices, can be extracted
<code>...</code>	some methods for this generic function require additional arguments.

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

**Examples**

```
## see the method function documentation
```

---

logDet.corStruct

---

*Extract corStruct Log-Determinant*

---

**Description**

This method function extracts the logarithm of the determinant of a square-root factor of the correlation matrix associated with `object`, or the sum of the log-determinants of square-root factors of the list of correlation matrices associated with `object`.

**Usage**

```
## S3 method for class 'corStruct':
logDet(object, covariate, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>corStruct</code> , representing a correlation structure.
<code>covariate</code>	an optional covariate vector (matrix), or list of covariate vectors (matrices), at which values the correlation matrix, or list of correlation matrices, are to be evaluated. Defaults to <code>getCovariate(object)</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

the log-determinant of a square-root factor of the correlation matrix associated with `object`, or the sum of the log-determinants of square-root factors of the list of correlation matrices associated with `object`.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

**Examples**

```
cs1 <- corAR1(0.3)
logDet(cs1, covariate = 1:4)
```

---

logDet.pdMat

*Extract Log-Determinant from a pdMat Object*

---

**Description**

This method function extracts the logarithm of the determinant of a square-root factor of the positive-definite matrix represented by `object`.

**Usage**

```
## S3 method for class 'pdMat':
logDet(object, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>pdMat</code> , representing a positive definite matrix.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

the log-determinant of a square-root factor of the positive-definite matrix represented by `object`.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates  
<bates@stat.wisc.edu>

**See Also**

[pdMat](#), [logDet](#)

**Examples**

```
pd1 <- pdSymm(diag(1:3))
logDet(pd1)
```

---

logDet.reStruct      *Extract reStruct Log-Determinants*

---

**Description**

Calculates, for each of the `pdMat` components of `object`, the logarithm of the determinant of a square-root factor.

**Usage**

```
## S3 method for class 'reStruct':
logDet(object, ...)
```

**Arguments**

`object`      an object inheriting from class `reStruct`, representing a random effects structure and consisting of a list of `pdMat` objects.

`...`      some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with the log-determinants of square-root factors of the `pdMat` components of `object`.

**Author(s)**

Jose Pinheiro

**See Also**

[reStruct](#), [pdMat](#), [logDet](#)

**Examples**

```
rs1 <- reStruct(list(A = pdSymm(diag(1:3)), form = ~Score),
  B = pdDiag(2 * diag(4), form = ~Educ))
logDet(rs1)
```

---

logLik.corStruct    *Extract corStruct Log-Likelihood*

---

### Description

This method function extracts the component of a Gaussian log-likelihood associated with the correlation structure, which is equal to the negative of the logarithm of the determinant (or sum of the logarithms of the determinants) of the matrix (or matrices) represented by `object`.

### Usage

```
## S3 method for class 'corStruct':  
logLik(object, data, ...)
```

### Arguments

<code>object</code>	an object inheriting from class <code>corStruct</code> , representing a correlation structure.
<code>data</code>	this argument is included to make this method function compatible with other <code>logLik</code> methods and will be ignored.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

### Value

the negative of the logarithm of the determinant (or sum of the logarithms of the determinants) of the correlation matrix (or matrices) represented by `object`.

### Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

### See Also

[logDet.corStruct](#), [logLik.lme](#),

### Examples

cs1 <- corAR1(0.2)  
cs1 <- Initialize(cs1, data = Orthodont)  
logLik(cs1)
```

---

logLik.glsStruct     *Log-Likelihood of a glsStruct Object*

---

### Description

`Pars` is used to update the coefficients of the model components of `object` and the individual (restricted) log-likelihood contributions of each component are added together. The type of log-likelihood (restricted or not) is determined by the `settings` attribute of `object`.

### Usage

```
## S3 method for class 'glsStruct':
logLik(object, Pars, conLin, ...)
```

### Arguments

<code>object</code>	an object inheriting from class <code>glsStruct</code> , representing a list of linear model components, such as <code>corStruct</code> and <code>varFunc</code> objects.
<code>Pars</code>	the parameter values at which the (restricted) log-likelihood is to be evaluated.
<code>conLin</code>	an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying linear model. Defaults to <code>attr(object, "conLin")</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

### Value

the (restricted) log-likelihood for the linear model described by `object`, evaluated at `Pars`.

### Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

### See Also

[gls](#), [glsStruct](#), [logLik.lme](#)

---

logLik.gnls     *Log-Likelihood of a gnls Object*

---

### Description

Returns the log-likelihood value of the nonlinear model represented by `object` evaluated at the estimated coefficients.

**Usage**

```
## S3 method for class 'gnls':
logLik(object, REML, ...)
```

**Arguments**

object	an object inheriting from class <code>gnls</code> , representing a generalized nonlinear least squares fitted model.
REML	an logical value for consistency with <code>logLik, gls</code> , but only <code>FALSE</code> is accepted..
...	some methods for this generic require additional arguments. None are used in this method.

**Value**

the log-likelihood of the linear model represented by `object` evaluated at the estimated coefficients.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[gnls](#), [logLik.lme](#)

**Examples**

fm1 <- gnls(weight ~ SSlogis(Time, Asym, xmid, scal), Soybean,
            weights = varPower())
logLik(fm1)
```

---

logLik.gnlsStruct *Log-Likelihood of a gnlsStruct Object*

---

**Description**

`Pars` is used to update the coefficients of the model components of `object` and the individual log-likelihood contributions of each component are added together.

**Usage**

```
## S3 method for class 'gnlsStruct':
logLik(object, Pars, conLin, ...)
```

**Arguments**

object	an object inheriting from class <code>gnlsStruct</code> , representing a list of model components, such as <code>corStruct</code> and <code>varFunc</code> objects, and attributes specifying the underlying nonlinear model and the response variable.
Pars	the parameter values at which the log-likelihood is to be evaluated.
conLin	an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying nonlinear model. Defaults to <code>attr(object, "conLin")</code> .
...	some methods for this generic require additional arguments. None are used in this method.

**Value**

the log-likelihood for the linear model described by `object`, evaluated at `Pars`.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

---

logLik.lme

*Log-Likelihood of an lme Object*

---

**Description**

If `REML=FALSE`, returns the log-likelihood value of the linear mixed-effects model represented by `object` evaluated at the estimated coefficients; else, the restricted log-likelihood evaluated at the estimated coefficients is returned.

**Usage**

```
## S3 method for class 'lme':
logLik(object, REML, ...)
```

**Arguments**

object	an object inheriting from class <code>lme</code> , representing a fitted linear mixed-effects model.
REML	an optional logical value. If <code>TRUE</code> the restricted log-likelihood is returned, else, if <code>FALSE</code> , the log-likelihood is returned. Defaults to the method of estimation used, that is <code>TRUE</code> if and only <code>object</code> was fitted with <code>method = "REML"</code> (the default for these fitting functions).
...	some methods for this generic require additional arguments. None are used in this method.

**Value**

the (restricted) log-likelihood of the model represented by `object` evaluated at the estimated coefficients.

**Author(s)**

Jose Pinheiro and Douglas Bates

---

`logLik.lmList`*Log-Likelihood of an lmList Object*

---

**Description**

If `pool=FALSE`, the (restricted) log-likelihoods of the `lm` components of `object` are summed together. Else, the (restricted) log-likelihood of the `lm` fit with different coefficients for each level of the grouping factor associated with the partitioning of the `object` components is obtained.

**Usage**

```
## S3 method for class 'lmList':  
logLik(object, REML, pool, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>lmList</code> , representing a list of <code>lm</code> objects with a common model.
<code>REML</code>	an optional logical value. If <code>TRUE</code> the restricted log-likelihood is returned, else, if <code>FALSE</code> , the log-likelihood is returned. Defaults to <code>FALSE</code> .
<code>pool</code>	an optional logical value indicating whether all <code>lm</code> components of <code>object</code> may be assumed to have the same error variance. Default is <code>attr(object, "pool")</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

either the sum of the (restricted) log-likelihoods of each `lm` component in `object`, or the (restricted) log-likelihood for the `lm` fit with separate coefficients for each component of `object`.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

**Examples**

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
logLik(fm1) # returns NA when it should not
```

---

logLik.reStruct      *Calculate reStruct Log-Likelihood*

---

**Description**

Calculates the log-likelihood, or restricted log-likelihood, of the Gaussian linear mixed-effects model represented by `object` and `conLin` (assuming spherical within-group covariance structure), evaluated at `coef(object)`. The `settings` attribute of `object` determines whether the log-likelihood, or the restricted log-likelihood, is to be calculated. The computational methods are described in Bates and Pinheiro (1998).

**Usage**

```
## S3 method for class 'reStruct':
logLik(object, conLin, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>reStruct</code> , representing a random effects structure and consisting of a list of <code>pdMat</code> objects.
<code>conLin</code>	a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

the log-likelihood, or restricted log-likelihood, of linear mixed-effects model represented by `object` and `conLin`, evaluated at `coef{object}`.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

---

logLik.varFunc      *Extract varFunc logLik*

---

### Description

This method function extracts the component of a Gaussian log-likelihood associated with the variance function structure represented by `object`, which is equal to the sum of the logarithms of the corresponding weights.

### Usage

```
## S3 method for class 'varFunc':  
logLik(object, data, ...)
```

### Arguments

<code>object</code>	an object inheriting from class <code>varFunc</code> , representing a variance function structure.
<code>data</code>	this argument is included to make this method function compatible with other <code>logLik</code> methods and will be ignored.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

### Value

the sum of the logarithms of the weights corresponding to the variance function structure represented by `object`.

### Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

### See Also

Machines

*Productivity Scores for Machines and Workers*

---

**Description**

The `Machines` data frame has 54 rows and 3 columns.

**Format**

This data frame contains the following columns:

**Worker** an ordered factor giving the unique identifier for the worker.

**Machine** a factor with levels A, B, and C identifying the machine brand.

**score** a productivity score.

**Details**

Data on an experiment to compare three brands of machines used in an industrial process are presented in Milliken and Johnson (p. 285, 1992). Six workers were chosen randomly among the employees of a factory to operate each machine three times. The response is an overall productivity score taking into account the number and quality of components produced.

---

MathAchieve

*Mathematics achievement scores*

---

**Description**

The `MathAchieve` data frame has 7185 rows and 6 columns.

**Format**

This data frame contains the following columns:

**School** an ordered factor identifying the school that the student attends

**Minority** a factor with levels `No` `Yes` indicating if the student is a member of a minority racial group.

**Sex** a factor with levels `Male` `Female`

**SES** a numeric vector of socio-economic status.

**MathAch** a numeric vector of mathematics achievement scores.

**MEANSES** a numeric vector of the mean SES for the school.

**Details**

Each row in this data frame contains the data for one student.

**Examples**

```
summary(MathAchieve)
```

---

MathAchSchool	<i>School demographic data for MathAchieve</i>
---------------	--

---

**Description**

The `MathAchSchool` data frame has 160 rows and 7 columns.

**Format**

This data frame contains the following columns:

**School** a factor giving the school on which the measurement is made.

**Size** a numeric vector giving the number of students in the school

**Sector** a factor with levels `Public Catholic`

**PRACAD** a numeric vector giving the percentage of students on the academic track

**DISCLIM** a numeric vector measuring the discrimination climate

**HIMINTY** a factor with levels `0 1`

**MEANSES** a numeric vector giving the mean SES score.

**Details**

These variables give the school-level demographic data to accompany the `MathAchieve` data.

---

<code>Matrix</code>	<i>Assign Matrix Values</i>
---------------------	-----------------------------

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `pdMat`, `pdBlocked`, and `reStruct`.

**Usage**

```
matrix(object) <- value
```

**Arguments**

`object` any object to which `as.matrix` can be applied.

`value` a matrix, or list of matrices, with the same dimensions as `as.matrix(object)` with the new values to be assigned to the matrix associated with `object`.

**Value**

will depend on the method function; see the appropriate documentation.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates  
<bates@stat.wisc.edu>

**See Also**

**Examples**

```
## see the method function documentation
```

---

Matrix.pdMat

*Assign Matrix to a pdMat Object*

---

**Description**

The positive-definite matrix represented by `object` is replaced by `value`. If the original matrix had row and/or column names, the corresponding names for `value` can either be `NULL`, or a permutation of the original names.

**Usage**

```
## S3 replacement method for class 'pdMat':  
matrix(object) <- value
```

**Arguments**

`object` an object inheriting from class `pdMat`, representing a positive definite matrix.  
`value` a matrix with the new values to be assigned to the positive-definite matrix represented by `object`. Must have the same dimensions as `as.matrix(object)`.

**Value**

a `pdMat` object similar to `object`, but with its coefficients modified to produce the matrix in `value`.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates  
<bates@stat.wisc.edu>

**See Also**

[pdMat, "matrix<-"](#)

## Examples

```
pd1 <- pdSymm(diag(3))
matrix(pd1) <- diag(1:3)
pd1
```

---

Matrix.reStruct      *Assign reStruct Matrices*

---

## Description

The individual matrices in `value` are assigned to each `pdMat` component of `object`, in the order they are listed. The new matrices must have the same dimensions as the matrices they are meant to replace.

## Usage

```
## S3 replacement method for class 'reStruct':
matrix(object) <- value
```

## Arguments

<code>object</code>	an object inheriting from class <code>reStruct</code> , representing a random effects structure and consisting of a list of <code>pdMat</code> objects.
<code>value</code>	a matrix, or list of matrices, with the new values to be assigned to the matrices associated with the <code>pdMat</code> components of <code>object</code> .

## Value

an `reStruct` object similar to `object`, but with the coefficients of the individual `pdMat` components modified to produce the matrices listed in `value`.

## Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

## See Also

## Examples

```
rs1 <- reStruct(list(Dog = ~day, Side = ~1), data = Pixel)
matrix(rs1) <- list(diag(2), 3)
```

Meat

*Tenderness of meat***Description**

The `Meat` data frame has 30 rows and 4 columns.

**Format**

This data frame contains the following columns:

**Storage** an ordered factor specifying the storage treatment - 1 (0 days), 2 (1 day), 3 (2 days), 4 (4 days), 5 (9 days), and 6 (18 days)

**score** a numeric vector giving the tenderness score of beef roast.

**Block** an ordered factor identifying the muscle from which the roast was extracted with levels `II < V < I < III < IV`

**Pair** an ordered factor giving the unique identifier for each pair of beef roasts with levels `II-1 < ... < IV-1`

**Details**

Cochran and Cox (section 11.51, 1957) describe data from an experiment conducted at Iowa State College (Paul, 1943) to compare the effects of length of cold storage on the tenderness of beef roasts. Six storage periods ranging from 0 to 18 days were used. Thirty roasts were scored by four judges on a scale from 0 to 10, with the score increasing with tenderness. The response was the sum of all four scores. Left and right roasts from the same animal were grouped into pairs, which were further grouped into five blocks, according to the muscle from which they were extracted. Different storage periods were applied to each roast within a pair according to a balanced incomplete block design.

Milk

*Protein content of cows' milk***Description**

The `Milk` data frame has 1337 rows and 4 columns.

**Format**

This data frame contains the following columns:

**protein** a numeric vector giving the protein content of the milk.

**Time** a numeric vector giving the time since calving (weeks).

**Cow** an ordered factor giving a unique identifier for each cow.

**Diet** a factor with levels `barley`, `barley+lupins`, and `lupins` identifying the diet for each cow.

## Details

Diggle, Liang, and Zeger (1994) describe data on the protein content of cows' milk in the weeks following calving. The cattle are grouped according to whether they are fed a diet with barley alone, with barley and lupins, or with lupins alone.

## Source

Diggle, Peter J., Liang, Kung-Yee and Zeger, Scott L. (1994), *Analysis of longitudinal data*, Oxford University Press, Oxford.

---

```
model.matrix.reStruct  
      reStruct Model Matrix
```

---

## Description

The model matrices for each element of `formula(object)`, calculated using `data`, are bound together column-wise. When multiple grouping levels are present (i.e. when `length(object) > 1`), the individual model matrices are combined from innermost (at the leftmost position) to outermost (at the rightmost position).

## Usage

```
## S3 method for class 'reStruct':  
model.matrix(object, data, contrast, ...)
```

## Arguments

<code>object</code>	an object inheriting from class <code>reStruct</code> , representing a random effects structure and consisting of a list of <code>pdMat</code> objects.
<code>data</code>	a data frame in which to evaluate the variables defined in <code>formula(object)</code> .
<code>contrast</code>	an optional named list specifying the contrasts to be used for representing the factor variables in <code>data</code> . The components names should match the names of the variables in <code>data</code> for which the contrasts are to be specified. The components of this list will be used as the <code>contrasts</code> attribute of the corresponding factor. If missing, the default contrast specification is used.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

## Value

a matrix obtained by binding together, column-wise, the model matrices for each element of `formula(object)`.

**Examples**

```
rs1 <- reStruct(list(Dog = ~day, Side = ~1), data = Pixel)
model.matrix(rs1, Pixel)
```

---

Muscle

*Contraction of heart muscle sections*

---

**Description**

The `Muscle` data frame has 60 rows and 3 columns.

**Format**

This data frame contains the following columns:

**Strip** an ordered factor indicating the strip of muscle being measured.

**conc** a numeric vector giving the concentration of  $\text{CaCl}_2$

**length** a numeric vector giving the shortening of the heart muscle strip.

**Details**

Baumann and Waldvogel (1963) describe data on the shortening of heart muscle strips dipped in a  $\text{CaCl}_2$  solution. The muscle strips are taken from the left auricle of a rat's heart.

---

Names

*Names Associated with an Object*

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `formula`, `modelStruct`, `pdBlocked`, `pdMat`, and `reStruct`.

**Usage**

```
Names(object, ...)
Names(object, ...) <- value
```

**Arguments**

object            any object for which names can be extracted and/or assigned.  
...                some methods for this generic function require additional arguments.  
value             names to be assigned to object.

**Value**

will depend on the method function used; see the appropriate documentation.

**SIDE EFFECTS**

On the left side of an assignment, sets the names associated with `object` to `value`, which must have an appropriate length.

**Note**

If names were generic, there would be no need for this generic function.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates  
<bates@stat.wisc.edu>

```

---

Names.formula            *Extract Names from a formula*

---

**Description**

This method function returns the names of the terms corresponding to the right hand side of `object` (treated as a linear formula), obtained as the column names of the corresponding `model.matrix`.

**Usage**

```
## S3 method for class 'formula':  
Names(object, data, exclude, ...)
```

**Arguments**

object	an object inheriting from class <code>formula</code> .
data	an optional data frame containing the variables specified in <code>object</code> . By default the variables are taken from the environment from which <code>Names.formula</code> is called.
exclude	an optional character vector with names to be excluded from the returned value. Default is <code>c("pi", ".")</code> .
...	some methods for this generic require additional arguments. None are used in this method.

**Value**

a character vector with the column names of the `model.matrix` corresponding to the right hand side of `object` which are not listed in `excluded`.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

**Examples**

```
Names(distance ~ Sex * age, data = Orthodont)
```

---

Names.pdBlocked      *Names of a pdBlocked Object*

---

**Description**

This method function extracts the first element of the `Dimnames` attribute, which contains the column names, for each block diagonal element in the matrix represented by `object`.

**Usage**

```
## S3 method for class 'pdBlocked':
Names(object, asList, ...)
```

**Arguments**

object	an object inheriting from class <code>pdBlocked</code> representing a positive-definite matrix with block diagonal structure
asList	a logical value. If <code>TRUE</code> a list with the names for each block diagonal element is returned. If <code>FALSE</code> a character vector with all column names is returned. Defaults to <code>FALSE</code> .
...	some methods for this generic require additional arguments. None are used in this method.

**Value**

if `asList` is `FALSE`, a character vector with column names of the matrix represented by `object`; otherwise, if `asList` is `TRUE`, a list with components given by the column names of the individual block diagonal elements in the matrix represented by `object`.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

pd1 <- pdBlocked(list(~Sex - 1, ~age - 1), data = Orthodont)
Names(pd1)
```

---

Names.pdMat

*Names of a pdMat Object*

---

**Description**

This method function returns the first element of the `Dimnames` attribute of `object`, which contains the column names of the matrix represented by `object`.

**Usage**

```
## S3 method for class 'pdMat':
Names(object, ...)
## S3 method for class 'pdMat':
Names(object, ...) <- value
```

**Arguments**

<code>object</code>	an object inheriting from class <code>pdMat</code> , representing a positive-definite matrix.
<code>value</code>	a character vector with the replacement values for the column and row names of the matrix represented by <code>object</code> . It must have length equal to the dimension of the matrix represented by <code>object</code> and, if names have been previously assigned to <code>object</code> , it must correspond to a permutation of the original names.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

if `object` has a `Dimnames` attribute then the first element of this attribute is returned; otherwise `NULL`.

**SIDE EFFECTS**

On the left side of an assignment, sets the `Dimnames` attribute of `object` to `list(value, value)`.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

---

Names.reStruct      *Names of an reStruct Object*

---

**Description**

This method function extracts the column names of each of the positive-definite matrices represented the `pdMat` elements of `object`.

**Usage**

```
## S3 method for class 'reStruct':
Names(object, ...)
## S3 method for class 'reStruct':
Names(object, ...) <- value
```

**Arguments**

<code>object</code>	an object inheriting from class <code>reStruct</code> , representing a random effects structure and consisting of a list of <code>pdMat</code> objects.
<code>value</code>	a list of character vectors with the replacement values for the names of the individual <code>pdMat</code> objects that form <code>object</code> . It must have the same length as <code>object</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a list containing the column names of each of the positive-definite matrices represented by the `pdMat` elements of `object`.

**SIDE EFFECTS**

On the left side of an assignment, sets the `Names` of the `pdMat` elements of `object` to the corresponding element of `value`.

**Author(s)**

```

---

needUpdate	<i>Check if Update is Needed</i>
------------	----------------------------------

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. By default, it tries to extract a `needUpdate` attribute of `object`. If this is `NULL` or `FALSE` it returns `FALSE`; else it returns `TRUE`. Updating of objects usually takes place in iterative algorithms in which auxiliary quantities associated with the object, and not being optimized over, may change.

**Usage**

```
needUpdate(object)
```

**Arguments**

`object` any object

**Value**

a logical value indicating whether `object` needs to be updated.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates  
<bates@stat.wisc.edu>

**See Also**

varStruct = varPower(form = ~age))  
needUpdate(lms1)
```

---

Nitrendipene

*Assay of nitrendipene*

---

### Description

The Nitrendipene data frame has 89 rows and 4 columns.

**Format**

This data frame contains the following columns:

**activity** a numeric vector

**NIF** a numeric vector

**Tissue** an ordered factor with levels 2 < 1 < 3 < 4

**log.NIF** a numeric vector

**Source**

Bates, D. M. and Watts, D. G. (1988), *Nonlinear Regression Analysis and Its Applications*, Wiley, New York.

---

 nlme

*Nonlinear Mixed-Effects Models*

---

**Description**

This generic function fits a nonlinear mixed-effects model in the formulation described in Lindstrom and Bates (1990) but allowing for nested random effects. The within-group errors are allowed to be correlated and/or have unequal variances.

**Usage**

```
nlme(model, data, fixed, random, groups, start, correlation, weights,
      subset, method, na.action, naPattern, control, verbose)
```

**Arguments**

- |        |  |
|--------|--|
| model  | a nonlinear model formula, with the response on the left of a <code>~</code> operator and an expression involving parameters and covariates on the right, or an <code>nlsList</code> object. If <code>data</code> is given, all names used in the formula should be defined as parameters or variables in the data frame. The method function <code>nlme.nlsList</code> is documented separately.  |
| data   | an optional data frame containing the variables named in <code>model</code> , <code>fixed</code> , <code>random</code> , <code>correlation</code> , <code>weights</code> , <code>subset</code> , and <code>naPattern</code> . By default the variables are taken from the environment from which <code>nlme</code> is called.  |
| fixed  | a two-sided linear formula of the form <code>f1+...+fn~x1+...+xm</code> , or a list of two-sided formulas of the form <code>f1~x1+...+xm</code> , with possibly different models for different parameters. The <code>f1, ..., fn</code> are the names of parameters included on the right hand side of <code>model</code> and the <code>x1+...+xm</code> expressions define linear models for these parameters (when the left hand side of the formula contains several parameters, they all are assumed to follow the same linear model, described by the right hand side expression). A <code>1</code> on the right hand side of the formula(s) indicates a single fixed effects for the corresponding parameter(s). |
| random | optionally, any of the following: (i) a two-sided formula of the form <code>r1+...+rn~x1+...+xm   g1/.../gQ</code> , with <code>r1, ..., rn</code> naming parameters included on the right hand side of <code>model</code> , <code>x1+...+xm</code> specifying the random-effects model for these parameters and <code>g1/.../gQ</code> the  |

grouping structure ( $Q$  may be equal to 1, in which case no  $/$  is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a two-sided formula of the form  $r_1 + \dots + r_n \sim x_1 + \dots + x_m$ , a list of two-sided formulas of the form  $r_1 \sim x_1 + \dots + x_m$ , with possibly different random-effects models for different parameters, a `pdMat` object with a two-sided formula, or list of two-sided formulas (i.e. a non-NULL value for `formula(random)`), or a list of `pdMat` objects with two-sided formulas, or lists of two-sided formulas. In this case, the grouping structure formula will be given in `groups`, or derived from the data used to fit the nonlinear mixed-effects model, which should inherit from class `groupedData`; (iii) a named list of formulas, lists of formulas, or `pdMat` objects as in (ii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the elements in the list; (iv) an `reStruct` object. See the documentation on `pdClasses` for a description of the available `pdMat` classes. Defaults to `fixed`, resulting in all fixed effects having also random effects.

<code>groups</code>	an optional one-sided formula of the form $\sim g_1$ (single level of nesting) or $\sim g_1 / \dots / g_Q$ (multiple levels of nesting), specifying the partitions of the data over which the random effects vary. $g_1, \dots, g_Q$ must evaluate to factors in <code>data</code> . The order of nesting, when multiple levels are present, is taken from left to right (i.e. $g_1$ is the first level, $g_2$ the second, etc.).
<code>start</code>	an optional numeric vector, or list of initial estimates for the fixed effects and random effects. If declared as a numeric vector, it is converted internally to a list with a single component <code>fixed</code> , given by the vector. The <code>fixed</code> component is required, unless the model function inherits from class <code>selfStart</code> , in which case initial values will be derived from a call to <code>nlsList</code> . An optional <code>random</code> component is used to specify initial values for the random effects and should consist of a matrix, or a list of matrices with length equal to the number of grouping levels. Each matrix should have as many rows as the number of groups at the corresponding level and as many columns as the number of random effects in that level.
<code>correlation</code>	an optional <code>corStruct</code> object describing the within-group correlation structure. See the documentation of <code>corClasses</code> for a description of the available <code>corStruct</code> classes. Defaults to <code>NULL</code> , corresponding to no within-group correlations.
<code>weights</code>	an optional <code>varFunc</code> object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to <code>varFixed</code> , corresponding to fixed variance weights. See the documentation on <code>varClasses</code> for a description of the available <code>varFunc</code> classes. Defaults to <code>NULL</code> , corresponding to homoscedastic within-group errors.
<code>subset</code>	an optional expression indicating the subset of the rows of <code>data</code> that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
<code>method</code>	a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "ML".
<code>na.action</code>	a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>nlme</code> to print an error message and terminate if there are any incomplete observations.
<code>naPattern</code>	an expression or formula object, specifying which returned values are to be regarded as missing.

<code>control</code>	a list of control values for the estimation algorithm to replace the default values returned by the function <code>nlmeControl</code> . Defaults to an empty list.
<code>verbose</code>	an optional logical value. If <code>TRUE</code> information on the evolution of the iterative algorithm is printed. Default is <code>FALSE</code> .

### Value

an object of class `nlme` representing the nonlinear mixed-effects model fit. Generic functions such as `print`, `plot` and `summary` have methods to show the results of the fit. See `nlmeObject` for the components of the fit. The functions `resid`, `coef`, `fitted`, `fixed.effects`, and `random.effects` can be used to extract some of its components.

            data = Loblolly,
            fixed = Asym + R0 + lrc ~ 1,
            random = Asym ~ 1,
            start = c(Asym = 103, R0 = -8.5, lrc = -3.3))
summary(fm1)
fm2 <- update(fm1, random = pdDiag(Asym + lrc ~ 1))
summary(fm2)

```

nlme.nlsList

*NLME fit from nlsList Object***Description**

If the random effects names defined in `random` are a subset of the `lmList` object coefficient names, initial estimates for the covariance matrix of the random effects are obtained (overwriting any values given in `random`). `formula(fixed)` and the `data` argument in the calling sequence used to obtain `fixed` are passed as the `fixed` and `data` arguments to `nlme.formula`, together with any other additional arguments in the function call. See the documentation on `nlme.formula` for a description of that function.

**Usage**

```

## S3 method for class 'nlsList':
nlme(model, data, fixed, random, groups, start, correlation, weights,
      subset, method, na.action, naPattern, control, verbose)

```

**Arguments**

<code>model</code>	an object inheriting from class <code>nlsList</code> , representing a list of <code>nls</code> fits with a common model.
<code>data</code>	this argument is included for consistency with the generic function. It is ignored in this method function.
<code>fixed</code>	this argument is included for consistency with the generic function. It is ignored in this method function.
<code>random</code>	an optional one-sided linear formula with no conditioning expression, or a <code>pdMat</code> object with a <code>formula</code> attribute. Multiple levels of grouping are not allowed with this method function. Defaults to a formula consisting of the right hand side of <code>formula(fixed)</code> .
<code>groups</code>	an optional one-sided formula of the form <code>~g1</code> (single level of nesting) or <code>~g1/.../gQ</code> (multiple levels of nesting), specifying the partitions of the data over which the random effects vary. <code>g1, ..., gQ</code> must evaluate to factors in <code>data</code> . The order of nesting, when multiple levels are present, is taken from left to right (i.e. <code>g1</code> is the first level, <code>g2</code> the second, etc.).
<code>start</code>	an optional numeric vector, or list of initial estimates for the fixed effects and random effects. If declared as a numeric vector, it is converted internally to a list with a single component <code>fixed</code> , given by the vector. The <code>fixed</code> component is required, unless the model function inherits from class <code>selfStart</code> , in which case initial values will be derived from a call to <code>nlsList</code> . An optional <code>random</code>

	component is used to specify initial values for the random effects and should consist of a matrix, or a list of matrices with length equal to the number of grouping levels. Each matrix should have as many rows as the number of groups at the corresponding level and as many columns as the number of random effects in that level.
<code>correlation</code>	an optional <code>corStruct</code> object describing the within-group correlation structure. See the documentation of <code>corClasses</code> for a description of the available <code>corStruct</code> classes. Defaults to <code>NULL</code> , corresponding to no within-group correlations.
<code>weights</code>	an optional <code>varFunc</code> object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to <code>varFixed</code> , corresponding to fixed variance weights. See the documentation on <code>varClasses</code> for a description of the available <code>varFunc</code> classes. Defaults to <code>NULL</code> , corresponding to homoscedastic within-group errors.
<code>subset</code>	an optional expression indicating the subset of the rows of <code>data</code> that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
<code>method</code>	a character string. If <code>"REML"</code> the model is fit by maximizing the restricted log-likelihood. If <code>"ML"</code> the log-likelihood is maximized. Defaults to <code>"ML"</code> .
<code>na.action</code>	a function that indicates what should happen when the data contain <code>NA</code> s. The default action ( <code>na.fail</code> ) causes <code>nlme</code> to print an error message and terminate if there are any incomplete observations.
<code>naPattern</code>	an expression or formula object, specifying which returned values are to be regarded as missing.
<code>control</code>	a list of control values for the estimation algorithm to replace the default values returned by the function <code>nlmeControl</code> . Defaults to an empty list.
<code>verbose</code>	an optional logical value. If <code>TRUE</code> information on the evolution of the iterative algorithm is printed. Default is <code>FALSE</code> .

## Value

an object of class `nlme` representing the linear mixed-effects model fit. Generic functions such as `print`, `plot` and `summary` have methods to show the results of the fit. See `nlmeObject` for the components of the fit. The functions `resid`, `coef`, `fitted`, `fixed.effects`, and `random.effects` can be used to extract some of its components.

---

nlmeControl

*Control Values for nlme Fit*

---

### Description

The values supplied in the function call replace the defaults and a list with all possible arguments is returned. The returned list is used as the `control` argument to the `nlme` function.

### Usage

```
nlmeControl(maxIter, pnlsMaxIter, msMaxIter, minScale,
            tolerance, niterEM, pnlsTol, msTol, msScale,
            returnObject, msVerbose, gradHess, apVar, .relStep,
            nlmStepMax = 100.0, minAbsParApVar = 0.05,
            opt = c("nlminb", "nlm"), natural = TRUE)
```

**Arguments**

maxIter	maximum number of iterations for the <code>nlme</code> optimization algorithm. Default is 50.
pnlsMaxIter	maximum number of iterations for the PNLs optimization step inside the <code>nlme</code> optimization. Default is 7.
msMaxIter	maximum number of iterations for the <code>nlm</code> optimization step inside the <code>nlme</code> optimization. Default is 50.
minScale	minimum factor by which to shrink the default step size in an attempt to decrease the sum of squares in the PNLs step. Default 0.001.
tolerance	tolerance for the convergence criterion in the <code>nlme</code> algorithm. Default is 1e-6.
niterEM	number of iterations for the EM algorithm used to refine the initial estimates of the random effects variance-covariance coefficients. Default is 25.
pnlsTol	tolerance for the convergence criterion in PNLs step. Default is 1e-3.
msTol	tolerance for the convergence criterion in <code>nlm</code> , passed as the <code>rel.tolerance</code> argument to the function (see documentation on <code>nlm</code> ). Default is 1e-7.
msScale	scale function passed as the <code>scale</code> argument to the <code>nlm</code> function (see documentation on that function). Default is <code>lmeScale</code> .
returnObject	a logical value indicating whether the fitted object should be returned when the maximum number of iterations is reached without convergence of the algorithm. Default is <code>FALSE</code> .
msVerbose	a logical value passed as the <code>trace</code> argument to <code>nlm</code> (see documentation on that function). Default is <code>FALSE</code> .
gradHess	a logical value indicating whether numerical gradient vectors and Hessian matrices of the log-likelihood function should be used in the <code>nlm</code> optimization. This option is only available when the correlation structure ( <code>corStruct</code> ) and the variance function structure ( <code>varFunc</code> ) have no "varying" parameters and the <code>pdMat</code> classes used in the random effects structure are <code>pdSymm</code> (general positive-definite), <code>pdDiag</code> (diagonal), <code>pdIdent</code> (multiple of the identity), or <code>pdCompSymm</code> (compound symmetry). Default is <code>TRUE</code> .
apVar	a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is <code>TRUE</code> .
.relStep	relative step for numerical derivatives calculations. Default is <code>.Machine\$double.eps^(1/3)</code> .
nlmStepMax	stepmax value to be passed to <code>nlm</code> . See <code>nlm</code> for details. Default is 100.0
minAbsParApVar	numeric value - minimum absolute parameter value in the approximate variance calculation. The default is 0.05.
opt	the optimizer to be used, either <code>nlminb</code> (the default since (R 2.2.0) or <code>nlm</code> (the previous default).
natural	a logical value indicating whether the <code>pdNatural</code> parametrization should be used for general positive-definite matrices ( <code>pdSymm</code> ) in <code>reStruct</code> , when the approximate covariance matrix of the estimators is calculated. Default is <code>TRUE</code> .

**Value**

a list with components for each of the possible arguments.

```

---

nlmeObject

*Fitted nlme Object*

---

**Description**

An object returned by the `nlme` function, inheriting from class `nlme`, also inheriting from class `lme`, and representing a fitted nonlinear mixed-effects model. Objects of this class have methods for the generic functions `anova`, `coef`, `fitted`, `fixed.effects`, `formula`, `getGroups`, `getResponse`, `intervals`, `logLik`, `pairs`, `plot`, `predict`, `print`, `random.effects`, `residuals`, `summary`, and `update`.

**Value**

The following components must be included in a legitimate `nlme` object.

<code>apVar</code>	an approximate covariance matrix for the variance-covariance coefficients. If <code>apVar = FALSE</code> in the list of control values used in the call to <code>nlme</code> , this component is equal to <code>NULL</code> .
<code>call</code>	a list containing an image of the <code>nlme</code> call that produced the object.
<code>coefficients</code>	a list with two components, <code>fixed</code> and <code>random</code> , where the first is a vector containing the estimated fixed effects and the second is a list of matrices with the estimated random effects for each level of grouping. For each matrix in the <code>random</code> list, the columns refer to the random effects and the rows to the groups.
<code>contrasts</code>	a list with the contrasts used to represent factors in the fixed effects formula and/or random effects formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the <code>nlme</code> model, this component will be an empty list.
<code>dims</code>	a list with basic dimensions used in the <code>nlme</code> fit, including the components <code>N</code> - the number of observations in the data, <code>Q</code> - the number of grouping levels, <code>qvec</code> - the number of random effects at each level from innermost to outermost (last two values are equal to zero and correspond to the fixed effects and the response), <code>ngrps</code> - the number of groups at each level from innermost to outermost (last two values are one and correspond to the fixed effects and the response), and <code>ncol</code> - the number of columns in the model matrix for each level of grouping from innermost to outermost (last two values are equal to the number of fixed effects and one).

fitted	a data frame with the fitted values as columns. The leftmost column corresponds to the population fixed effects (corresponding to the fixed effects only) and successive columns from left to right correspond to increasing levels of grouping.
fixDF	a list with components <code>X</code> and <code>terms</code> specifying the denominator degrees of freedom for, respectively, t-tests for the individual fixed effects and F-tests for the fixed-effects terms in the models.
groups	a data frame with the grouping factors as columns. The grouping level increases from left to right.
logLik	the (restricted) log-likelihood at convergence.
map	a list with components <code>fmap</code> , <code>rmap</code> , <code>rmapRel</code> , and <code>bmap</code> , specifying various mappings for the fixed and random effects, used to generate predictions from the fitted object.
method	the estimation method: either "ML" for maximum likelihood, or "REML" for restricted maximum likelihood.
modelStruct	an object inheriting from class <code>nlmeStruct</code> , representing a list of mixed-effects model components, such as <code>reStruct</code> , <code>corStruct</code> , and <code>varFunc</code> objects.
numIter	the number of iterations used in the iterative algorithm.
residuals	a data frame with the residuals as columns. The leftmost column corresponds to the population residuals and successive columns from left to right correspond to increasing levels of grouping.
sigma	the estimated within-group error standard deviation.
varFix	an approximate covariance matrix of the fixed effects estimates.

---

nlmeStruct

*Nonlinear Mixed-Effects Structure*

---

**Description**

A nonlinear mixed-effects structure is a list of model components representing different sets of parameters in the nonlinear mixed-effects model. An `nlmeStruct` list must contain at least a `reStruct` object, but may also contain `corStruct` and `varFunc` objects. NULL arguments are not included in the `nlmeStruct` list.

**Usage**

```
nlmeStruct(reStruct, corStruct, varStruct)
```

**Arguments**

<code>reStruct</code>	a <code>reStruct</code> representing a random effects structure.
<code>corStruct</code>	an optional <code>corStruct</code> object, representing a correlation structure. Default is <code>NULL</code> .
<code>varStruct</code>	an optional <code>varFunc</code> object, representing a variance function structure. Default is <code>NULL</code> .

**Value**

a list of model components determining the parameters to be estimated for the associated nonlinear mixed-effects model.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

**Examples**

```
nlms1 <- nlmeStruct(reStruct(~age), corAR1(), varPower())
```

---

nlsList

*List of nls Objects with a Common Model*

---

**Description**

Data is partitioned according to the levels of the grouping factor defined in `model` and individual `nls` fits are obtained for each data partition, using the model defined in `model`.

**Usage**

```
nlsList(model, data, start, control, level, subset, na.action, pool)
## S3 method for class 'nlsList':
update(object, model., ..., evaluate = TRUE)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>nlsList</code> , representing a list of fitted <code>nls</code> objects.
<code>model</code>	either a nonlinear model formula, with the response on the left of a <code>~</code> operator and an expression involving parameters, covariates, and a grouping factor separated by the <code> </code> operator on the right, or a <code>selfStart</code> function. The method function <code>nlsList.selfStart</code> is documented separately.
<code>model.</code>	Changes to the model – see <code>update.formula</code> for details.
<code>data</code>	a data frame in which to interpret the variables named in <code>model</code> .

start	an optional named list with initial values for the parameters to be estimated in <code>model</code> . It is passed as the <code>start</code> argument to each <code>nls</code> call and is required when the nonlinear function in <code>model</code> does not inherit from class <code>selfStart</code> .
control	a list of control values passed as the <code>control</code> argument to <code>nls</code> . Defaults to an empty list.
level	an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.
subset	an optional expression indicating the subset of the rows of <code>data</code> that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
na.action	a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>nlsList</code> to print an error message and terminate if there are any incomplete observations.
pool	an optional logical value that is preserved as an attribute of the returned value. This will be used as the default for <code>pool</code> in calculations of standard deviations or standard errors for summaries.
...	some methods for this generic require additional arguments. None are used in this method.
evaluate	If <code>TRUE</code> evaluate the new call else return the call.

### Value

a list of `nls` objects with as many components as the number of groups defined by the grouping factor. Generic functions such as `coef`, `fixed.effects`, `lme`, `pairs`, `plot`, `predict`, `random.effects`, `summary`, and `update` have methods that can be applied to an `nlsList` object.

### Examples

```
fml <- nlsList(uptake ~ SSasymOff(conc, Asym, lrc, c0),
  data = CO2, start = c(Asym = 30, lrc = -4.5, c0 = 52))
summary(fml)
```

---

`nlsList.selfStart` *nlsList Fit from a selfStart Function*

---

### Description

The response variable and primary covariate in `formula(data)` are used together with `model` to construct the nonlinear model formula. This is used in the `nls` calls and, because a selfStarting model function can calculate initial estimates for its parameters from the data, no starting estimates need to be provided.

## Usage

```
## S3 method for class 'selfStart':  
nlsList(model, data, start, control, level, subset, na.action, pool)
```

## Arguments

<code>model</code>	a <code>selfStart</code> model function, which calculates initial estimates for the model parameters from <code>data</code> .
<code>data</code>	a data frame in which to interpret the variables in <code>model</code> . Because no grouping factor can be specified in <code>model</code> , <code>data</code> must inherit from class <code>groupedData</code> .
<code>start</code>	an optional named list with initial values for the parameters to be estimated in <code>model</code> . It is passed as the <code>start</code> argument to each <code>nls</code> call and is required when the nonlinear function in <code>model</code> does not inherit from class <code>selfStart</code> .
<code>control</code>	a list of control values passed as the <code>control</code> argument to <code>nls</code> . Defaults to an empty list.
<code>level</code>	an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.
<code>subset</code>	an optional expression indicating the subset of the rows of <code>data</code> that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
<code>na.action</code>	a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>nlsList</code> to print an error message and terminate if there are any incomplete observations.
<code>pool</code>	an optional logical value that is preserved as an attribute of the returned value. This will be used as the default for <code>pool</code> in calculations of standard deviations or standard errors for summaries.

## Value

a list of `nls` objects with as many components as the number of groups defined by the grouping factor. A `NULL` value is assigned to the components corresponding to clusters for which the `nls` algorithm failed to converge. Generic functions such as `coef`, `fixed.effects`, `lme`, `pairs`, `plot`, `predict`, `random.effects`, `summary`, and `update` have methods that can be applied to an `nlsList` object.

```

Oats

*Split-plot Experiment on Varieties of Oats***Description**

The `Oats` data frame has 72 rows and 4 columns.

**Format**

This data frame contains the following columns:

**Block** an ordered factor with levels VI < V < III < IV < II < I

**Variety** a factor with levels Golden Rain Marvellous Victory

**nitro** a numeric vector

**yield** a numeric vector

**Details**

These data have been introduced by Yates (1935) as an example of a split-plot design. The treatment structure used in the experiment was a  $3 \times 4$  full factorial, with three varieties of oats and four concentrations of nitrogen. The experimental units were arranged into six blocks, each with three whole-plots subdivided into four subplots. The varieties of oats were assigned randomly to the whole-plots and the concentrations of nitrogen to the subplots. All four concentrations of nitrogen were used on each whole-plot.

Orthodont

*Growth curve data on an orthodontic measurement***Description**

The `Orthodont` data frame has 108 rows and 4 columns of the change in an orthodontic measurement over time for several young subjects.

**Format**

This data frame contains the following columns:

**distance** a numeric vector of distances from the pituitary to the pterygomaxillary fissure (mm). These distances are measured on x-ray images of the skull.

**age** a numeric vector of ages of the subject (yr).

**Subject** an ordered factor indicating the subject on which the measurement was made. The levels are labelled M01 to M16 for the males and F01 to F13 for the females. The ordering is by increasing average distance within sex.

**Sex** a factor with levels Male and Female

**Details**

Investigators at the University of North Carolina Dental School followed the growth of 27 children (16 males, 11 females) from age 8 until age 14. Every two years they measured the distance between the pituitary and the pterygomaxillary fissure, two points that are easily identified on x-ray exposures of the side of the head.

 Ovary

---

*Counts of Ovarian Follicles*

---

**Description**

The Ovary data frame has 308 rows and 3 columns.

**Format**

This data frame contains the following columns:

**Mare** an ordered factor indicating the mare on which the measurement is made.

**Time** time in the estrus cycle. The data were recorded daily from 3 days before ovulation until 3 days after the next ovulation. The measurement times for each mare are scaled so that the ovulations for each mare occur at times 0 and 1.

**follicles** the number of ovarian follicles greater than 10 mm in diameter.

**Details**

Pierson and Ginther (1987) report on a study of the number of large ovarian follicles detected in different mares at several times in their estrus cycles.

**Source**

---

Oxboys

*Heights of Boys in Oxford*

---

### Description

The Oxboys data frame has 234 rows and 4 columns.

### Format

This data frame contains the following columns:

**Subject** an ordered factor giving a unique identifier for each boy in the experiment

**age** a numeric vector giving the standardized age (dimensionless)

**height** a numeric vector giving the height of the boy (cm)

**Occasion** an ordered factor - the result of converting age from a continuous variable to a count so these slightly unbalanced data can be analyzed as balanced.

### Details

These data are described in Goldstein (1987) as data on the height of a selection of boys from Oxford, England versus a standardized age.

### Source

---

Oxide

*Variability in Semiconductor Manufacturing*

---

### Description

The Oxide data frame has 72 rows and 5 columns.

### Format

This data frame contains the following columns:

**Source** a factor with levels 1 and 2

**Lot** a factor giving a unique identifier for each lot.

**Wafer** a factor giving a unique identifier for each wafer within a lot.

**Site** a factor with levels 1, 2, and 3

**Thickness** a numeric vector giving the thickness of the oxide layer.

**Details**

These data are described in Littell et al. (1996, p. 155) as coming “from a passive data collection study in the semiconductor industry where the objective is to estimate the variance components to determine the assignable causes of the observed variability.” The observed response is the thickness of the oxide layer on silicon wafers, measured at three different sites of each of three wafers selected from each of eight lots sampled from the population of lots.

pairs.compareFits *Pairs Plot of compareFits Object*

---

**Description**

Scatter plots of the values being compared are generated for each pair of coefficients in  $x$ . Different symbols (colors) are used for each object being compared and values corresponding to the same group are joined by a line, to facilitate comparison of fits. If only two coefficients are present, the `trellis` function `xyplot` is used; otherwise the `trellis` function `splom` is used.

**Usage**

```
## S3 method for class 'compareFits':
pairs(x, subset, key, ...)
```

**Arguments**

<code>x</code>	an object of class <code>compareFits</code> .
<code>subset</code>	an optional logical or integer vector specifying which rows of <code>x</code> should be used in the plots. If missing, all rows are used.
<code>key</code>	an optional logical value, or list. If <code>TRUE</code> , a legend is included at the top of the plot indicating which symbols (colors) correspond to which objects being compared. If <code>FALSE</code> , no legend is included. If given as a list, <code>key</code> is passed down as an argument to the <code>trellis</code> function generating the plots ( <code>splom</code> or <code>xyplot</code> ). Defaults to <code>TRUE</code> .
<code>...</code>	optional arguments passed down to the <code>trellis</code> function generating the plots.

**Value**

Pairwise scatter plots of the values being compared, with different symbols (colors) used for each object under comparison.

**Author(s)**

Jose Pinheiro and Douglas Bates

**Examples**

```
fm1 <- lmList(Orthodont)
fm2 <- lme(Orthodont)
pairs(compareFits(coef(fm1), coef(fm2)))
```

---

pairs.lme

*Pairs Plot of an lme Object*

---

**Description**

Diagnostic plots for the linear mixed-effects fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. The expression on the right hand side of the formula, before a `|` operator, must evaluate to a data frame with at least two columns. If the data frame has two columns, a scatter plot of the two variables is displayed (the Trellis function `xyplot` is used). Otherwise, if more than two columns are present, a scatter plot matrix with pairwise scatter plots of the columns in the data frame is displayed (the Trellis function `spIom` is used).

**Usage**

```
## S3 method for class 'lme':
pairs(x, form, label, id, idLabels, grid, ...)
```

**Arguments**

<code>x</code>	an object inheriting from class <code>lme</code> , representing a fitted linear mixed-effects model.
<code>form</code>	an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain <code>x</code> can be referenced. In addition, <code>x</code> itself can be referenced in the formula using the symbol <code>"."</code> . Conditional expressions on the right of a <code> </code> operator can be used to define separate panels in a Trellis display. The expression on the right hand side of <code>form</code> , and to the left of the <code> </code> operator, must evaluate to a data frame with at least two columns. Default is <code>~ coef(.)</code> , corresponding to a pairs plot of the coefficients evaluated at the innermost level of nesting.
<code>label</code>	an optional character vector of labels for the variables in the pairs plot.
<code>id</code>	an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for an outlier test based on the Mahalanobis distances of the estimated random effects. Groups with random effects distances greater than the $1 - \text{value}$ percentile of the appropriate chi-square distribution are identified in the plot using <code>idLabels</code> . If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify points in the plot. If missing, no points are identified.

`idLabels` an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the points identified according to `id`. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified points. Default is the innermost grouping factor.

`grid` an optional logical value indicating whether a grid should be added to plot. Default is `FALSE`.

`...` optional arguments passed to the Trellis plot function.

**Value**

a diagnostic Trellis plot.

PBG

*Effect of Phenylbiguanide on Blood Pressure***Description**

The PBG data frame has 60 rows and 5 columns.

**Format**

This data frame contains the following columns:

**deltaBP** a numeric vector

**dose** a numeric vector

**Run** an ordered factor with levels T5 < T4 < T3 < T2 < T1 < P5 < P3 < P2 < P4 < P1

**Treatment** a factor with levels MDL 72222 Placebo

**Rabbit** an ordered factor with levels 5 < 3 < 2 < 4 < 1

**Details**

Data on an experiment to examine the effect of a antagonist MDL 72222 on the change in blood pressure experienced with increasing dosage of phenylbiguanide are described in Ludbrook (1994) and analyzed in Venables and Ripley (1999, section 8.8). Each of five rabbits was exposed to increasing doses of phenylbiguanide after having either a placebo or the HD5-antagonist MDL 72222 administered.

pdBlocked

*Positive-Definite Block Diagonal Matrix***Description**

This function is a constructor for the pdBlocked class, representing a positive-definite block-diagonal matrix. Each block-diagonal element of the underlying matrix is itself a positive-definite matrix and is represented internally as an individual pdMat object. When value is numeric(0), a list of uninitialized pdMat objects, a list of one-sided formulas, or a list of vectors of character strings, object is returned as an uninitialized pdBlocked object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the coef or matrix replacement functions. If value is a list of initialized pdMat objects, object will be constructed from the list obtained by applying as.matrix to each of the pdMat elements of value. Finally, if value is a list of numeric vectors, they are assumed to represent the unrestricted coefficients of the block-diagonal elements of the underlying positive-definite matrix.

## Usage

```
pdBlocked(value, form, nam, data, pdClass)
```

## Arguments

- |         |  |
|---------|--|
| value   | an optional list with elements to be used as the <code>value</code> argument to other <code>pdMat</code> constructors. These include: <code>pdMat</code> objects, positive-definite matrices, one-sided linear formulas, vectors of character strings, or numeric vectors. All elements in the list must be similar (e.g. all one-sided formulas, or all numeric vectors). Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object. |
| form    | an optional list of one-sided linear formulas specifying the row/column names for the block-diagonal elements of the matrix represented by <code>object</code> . Because factors may be present in <code>form</code> , the formulas needs to be evaluated on a <code>data.frame</code> to resolve the names they define. This argument is ignored when <code>value</code> is a list of one-sided formulas. Defaults to <code>NULL</code> .                 |
| nam     | an optional list of vector of character strings specifying the row/column names for the block-diagonal elements of the matrix represented by <code>object</code> . Each of its components must have length equal to the dimension of the corresponding block-diagonal element and unreplicated elements. This argument is ignored when <code>value</code> is a list of vector of character strings. Defaults to <code>NULL</code> .                        |
| data    | an optional data frame in which to evaluate the variables named in <code>value</code> and <code>form</code> . It is used to obtain the levels for <code>factors</code> , which affect the dimensions and the row/column names of the underlying matrix. If <code>NULL</code> , no attempt is made to obtain information on any <code>factors</code> appearing in the formulas. Defaults to the parent frame from which the function was called.            |
| pdClass | an optional vector of character strings naming the <code>pdMat</code> classes to be assigned to the individual blocks in the underlying matrix. If a single class is specified, it is used for all block-diagonal elements. This argument will only be used when <code>value</code> is missing, or its elements are not <code>pdMat</code> objects. Defaults to <code>"pdSymm"</code> .  |

## Value

a `pdBlocked` object representing a positive-definite block-diagonal matrix, also inheriting from class `pdMat`.

**Examples**

```
pd1 <- pdBlocked(list(diag(1:2), diag(c(0.1, 0.2, 0.3))),
                 nam = list(c("A", "B"), c("a1", "a2", "a3")))
pd1
```

---

 pdClasses

*Positive-Definite Matrix Classes*

---

**Description**

Standard classes of positive-definite matrices (pdMat) structures available in the nlme library.

**Value**

Available standard classes:

pdSymm	general positive-definite matrix, with no additional structure
pdLogChol	general positive-definite matrix, with no additional structure, using a log-Cholesky parameterization
pdDiag	diagonal
pdIdent	multiple of an identity
pdCompSymm	compound symmetry structure (constant diagonal and constant off-diagonal elements)
pdBlocked	block-diagonal matrix, with diagonal blocks of any "atomic" pdMat class
pdNatural	general positive-definite matrix in natural parametrization (i.e. parametrized in terms of standard deviations and correlations). The underlying coefficients are not unrestricted, so this class should NOT be used for optimization.

**Note**

Users may define their own pdMat classes by specifying a constructor function and, at a minimum, methods for the functions pdConstruct, pdMatrix and coef. For examples of these functions, see the methods for classes pdSymm and pdDiag.

`pdCompSymm`*Positive-Definite Matrix with Compound Symmetry Structure*

---

### Description

This function is a constructor for the `pdCompSymm` class, representing a positive-definite matrix with compound symmetry structure (constant diagonal and constant off-diagonal elements). The underlying matrix is represented by 2 unrestricted parameters. When `value` is `numeric(0)`, an uninitialized `pdMat` object, a one-sided formula, or a vector of character strings, `object` is returned as an uninitialized `pdCompSymm` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is an initialized `pdMat` object, `object` will be constructed from `as.matrix(value)`. Finally, if `value` is a numeric vector of length 2, it is assumed to represent the unrestricted coefficients of the underlying positive-definite matrix.

### Usage

```
pdCompSymm(value, form, nam, data)
```

### Arguments

<code>value</code>	an optional initialization value, which can be any of the following: a <code>pdMat</code> object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector of length 2. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.
<code>form</code>	an optional one-sided linear formula specifying the row/column names for the matrix represented by <code>object</code> . Because factors may be present in <code>form</code> , the formula needs to be evaluated on a <code>data.frame</code> to resolve the names it defines. This argument is ignored when <code>value</code> is a one-sided formula. Defaults to <code>NULL</code> .
<code>nam</code>	an optional vector of character strings specifying the row/column names for the matrix represented by <code>object</code> . It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when <code>value</code> is a vector of character strings. Defaults to <code>NULL</code> .
<code>data</code>	an optional data frame in which to evaluate the variables named in <code>value</code> and <code>form</code> . It is used to obtain the levels for <code>factors</code> , which affect the dimensions and the row/column names of the underlying matrix. If <code>NULL</code> , no attempt is made to obtain information on <code>factors</code> appearing in the formulas. Defaults to the parent frame from which the function was called.

### Value

a `pdCompSymm` object representing a positive-definite matrix with compound symmetry structure, also inheriting from class `pdMat`.

### Author(s)

pd1
```

---

pdConstruct

*Construct pdMat Objects*

---

## Description

This function is an alternative constructor for the `pdMat` class associated with `object` and is mostly used internally in other functions. See the documentation on the principal constructor function, generally with the same name as the `pdMat` class of `object`.

## Usage

```
pdConstruct(object, value, form, nam, data, ...)
```

## Arguments

<code>object</code>	an object inheriting from class <code>pdMat</code> , representing a positive definite matrix.
<code>value</code>	an optional initialization value, which can be any of the following: a <code>pdMat</code> object, a positive-definite matrix, a one-sided linear formula (with variables separated by <code>+</code> ), a vector of character strings, or a numeric vector. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.
<code>form</code>	an optional one-sided linear formula specifying the row/column names for the matrix represented by <code>object</code> . Because factors may be present in <code>form</code> , the formula needs to be evaluated on a <code>data.frame</code> to resolve the names it defines. This argument is ignored when <code>value</code> is a one-sided formula. Defaults to <code>NULL</code> .
<code>nam</code>	an optional vector of character strings specifying the row/column names for the matrix represented by <code>object</code> . It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when <code>value</code> is a vector of character strings. Defaults to <code>NULL</code> .
<code>data</code>	an optional data frame in which to evaluate the variables named in <code>value</code> and <code>form</code> . It is used to obtain the levels for <code>factors</code> , which affect the dimensions and the row/column names of the underlying matrix. If <code>NULL</code> , no attempt is made to obtain information on <code>factors</code> appearing in the formulas. Defaults to the parent frame from which the function was called.
<code>...</code>	optional arguments for some methods.

**Value**

a `pdMat` object representing a positive-definite matrix, inheriting from the same classes as `object`.

**Examples**

```
pd1 <- pdSymm()
pdConstruct(pd1, diag(1:4))
```

---

`pdConstruct.pdBlocked`

*Construct pdBlocked Objects*

---

**Description**

This function give an alternative constructor for the `pdBlocked` class, representing a positive-definite block-diagonal matrix. Each block-diagonal element of the underlying matrix is itself a positive-definite matrix and is represented internally as an individual `pdMat` object. When `value` is `numeric(0)`, a list of uninitialized `pdMat` objects, a list of one-sided formulas, or a list of vectors of character strings, `object` is returned as an uninitialized `pdBlocked` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is a list of initialized `pdMat` objects, `object` will be constructed from the list obtained by applying `as.matrix` to each of the `pdMat` elements of `value`. Finally, if `value` is a list of numeric vectors, they are assumed to represent the unrestricted coefficients of the block-diagonal elements of the underlying positive-definite matrix.

**Usage**

```
## S3 method for class 'pdBlocked':
pdConstruct(object, value, form, nam, data, pdClass,
...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>pdBlocked</code> , representing a positive definite block-diagonal matrix.
<code>value</code>	an optional list with elements to be used as the <code>value</code> argument to other <code>pdMat</code> constructors. These include: <code>pdMat</code> objects, positive-definite matrices, one-sided linear formulas, vectors of character strings, or numeric vectors. All elements in the list must be similar (e.g. all one-sided formulas, or all numeric vectors). Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.

<code>form</code>	an optional list of one-sided linear formula specifying the row/column names for the block-diagonal elements of the matrix represented by <code>object</code> . Because factors may be present in <code>form</code> , the formulas needs to be evaluated on a <code>data.frame</code> to resolve the names they defines. This argument is ignored when <code>value</code> is a list of one-sided formulas. Defaults to <code>NULL</code> .
<code>nam</code>	an optional list of vector of character strings specifying the row/column names for the block-diagonal elements of the matrix represented by <code>object</code> . Each of its components must have length equal to the dimension of the corresponding block-diagonal element and unreplicated elements. This argument is ignored when <code>value</code> is a list of vector of character strings. Defaults to <code>NULL</code> .
<code>data</code>	an optional data frame in which to evaluate the variables named in <code>value</code> and <code>form</code> . It is used to obtain the levels for <code>factors</code> , which affect the dimensions and the row/column names of the underlying matrix. If <code>NULL</code> , no attempt is made to obtain information on <code>factors</code> appearing in the formulas. Defaults to the parent frame from which the function was called.
<code>pdClass</code>	an optional vector of character strings naming the <code>pdMat</code> classes to be assigned to the individual blocks in the underlying matrix. If a single class is specified, it is used for all block-diagonal elements. This argument will only be used when <code>value</code> is missing, or its elements are not <code>pdMat</code> objects. Defaults to <code>"pdSymm"</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

### Value

a `pdBlocked` object representing a positive-definite block-diagonal matrix, also inheriting from class `pdMat`.

```

---

`pdDiag`*Diagonal Positive-Definite Matrix*

---

### Description

This function is a constructor for the `pdDiag` class, representing a diagonal positive-definite matrix. If the matrix associated with `object` is of dimension  $n$ , it is represented by  $n$  unrestricted parameters, given by the logarithm of the square-root of the diagonal values. When `value` is `numeric(0)`, an uninitialized `pdMat` object, a one-sided formula, or a vector of character strings, `object` is returned as an uninitialized `pdDiag` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is an initialized `pdMat` object, `object` will be constructed from `as.matrix(value)`. Finally, if `value` is a numeric vector, it is assumed to represent the unrestricted coefficients of the underlying positive-definite matrix.

### Usage

```
pdDiag(value, form, nam, data)
```

### Arguments

<code>value</code>	an optional initialization value, which can be any of the following: a <code>pdMat</code> object, a positive-definite matrix, a one-sided linear formula (with variables separated by <code>+</code> ), a vector of character strings, or a numeric vector of length equal to the dimension of the underlying positive-definite matrix. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.
<code>form</code>	an optional one-sided linear formula specifying the row/column names for the matrix represented by <code>object</code> . Because factors may be present in <code>form</code> , the formula needs to be evaluated on a <code>data.frame</code> to resolve the names it defines. This argument is ignored when <code>value</code> is a one-sided formula. Defaults to <code>NULL</code> .
<code>nam</code>	an optional vector of character strings specifying the row/column names for the matrix represented by <code>object</code> . It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when <code>value</code> is a vector of character strings. Defaults to <code>NULL</code> .
<code>data</code>	an optional data frame in which to evaluate the variables named in <code>value</code> and <code>form</code> . It is used to obtain the levels for <code>factors</code> , which affect the dimensions and the row/column names of the underlying matrix. If <code>NULL</code> , no attempt is made to obtain information on <code>factors</code> appearing in the formulas. Defaults to the parent frame from which the function was called.

### Value

a `pdDiag` object representing a diagonal positive-definite matrix, also inheriting from class `pdMat`.

### Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

pd1
```

---

pdFactor

*Square-Root Factor of a Positive-Definite Matrix*

---

**Description**

A square-root factor of the positive-definite matrix represented by `object` is obtained. Letting  $\Sigma$  denote a positive-definite matrix, a square-root factor of  $\Sigma$  is any square matrix  $L$  such that  $\Sigma = L'L$ . This function extracts  $L$ .

**Usage**

```
pdFactor(object)
```

**Arguments**

`object` an object inheriting from class `pdMat`, representing a positive definite matrix, which must have been initialized (i.e. `length(coef(object)) > 0`).

**Value**

a vector with a square-root factor of the positive-definite matrix associated with `object` stacked column-wise.

**Note**

This function is used intensively in optimization algorithms and its value is returned as a vector for efficiency reasons. The `pdMatrix` function can be used to obtain square-root factors in matrix form.

---

pdFactor.reStruct *Extract Square-Root Factor from Components of an reStruct Object*

---

**Description**

This method function extracts square-root factors of the positive-definite matrices corresponding to the pdMat elements of object.

**Usage**

```
## S3 method for class 'reStruct':
pdFactor(object)
```

**Arguments**

object            an object inheriting from class reStruct, representing a random effects structure and consisting of a list of pdMat objects.

**Value**

a vector with square-root factors of the positive-definite matrices corresponding to the elements of object stacked column-wise.

**Note**

This function is used intensively in optimization algorithms and its value is returned as a vector for efficiency reasons. The pdMatrix function can be used to obtain square-root factors in matrix form.

pdFactor(rs1)
```

pdIdent

*Multiple of the Identity Positive-Definite Matrix***Description**

This function is a constructor for the `pdIdent` class, representing a multiple of the identity positive-definite matrix. The matrix associated with `object` is represented by 1 unrestricted parameter, given by the logarithm of the square-root of the diagonal value. When `value` is `numeric(0)`, an uninitialized `pdMat` object, a one-sided formula, or a vector of character strings, `object` is returned as an uninitialized `pdIdent` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is an initialized `pdMat` object, `object` will be constructed from `as.matrix(value)`. Finally, if `value` is a numeric value, it is assumed to represent the unrestricted coefficient of the underlying positive-definite matrix.

**Usage**

```
pdIdent(value, form, nam, data)
```

**Arguments**

<code>value</code>	an optional initialization value, which can be any of the following: a <code>pdMat</code> object, a positive-definite matrix, a one-sided linear formula (with variables separated by <code>+</code> ), a vector of character strings, or a numeric value. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.
<code>form</code>	an optional one-sided linear formula specifying the row/column names for the matrix represented by <code>object</code> . Because factors may be present in <code>form</code> , the formula needs to be evaluated on a <code>data.frame</code> to resolve the names it defines. This argument is ignored when <code>value</code> is a one-sided formula. Defaults to <code>NULL</code> .
<code>nam</code>	an optional vector of character strings specifying the row/column names for the matrix represented by <code>object</code> . It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when <code>value</code> is a vector of character strings. Defaults to <code>NULL</code> .
<code>data</code>	an optional data frame in which to evaluate the variables named in <code>value</code> and <code>form</code> . It is used to obtain the levels for <code>factors</code> , which affect the dimensions and the row/column names of the underlying matrix. If <code>NULL</code> , no attempt is made to obtain information on <code>factors</code> appearing in the formulas. Defaults to the parent frame from which the function was called.

**Value**

a `pdIdent` object representing a multiple of the identity positive-definite matrix, also inheriting from class `pdMat`.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**References**

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

**See Also**

**Examples**

```
pd1 <- pdIdent(4 * diag(3), nam = c("A", "B", "C"))
pd1
```

---

pdLogChol

*General Positive-Definite Matrix*

---

**Description**

This function is a constructor for the `pdLogChol` class, representing a general positive-definite matrix. If the matrix associated with `object` is of dimension  $n$ , it is represented by  $n(n + 1)/2$  unrestricted parameters, using the log-Cholesky parametrization described in Pinheiro and Bates (1996). When `value` is `numeric(0)`, an uninitialized `pdMat` object, a one-sided formula, or a vector of character strings, `object` is returned as an uninitialized `pdLogChol` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is an initialized `pdMat` object, `object` will be constructed from `as.matrix(value)`. Finally, if `value` is a numeric vector, it is assumed to represent the unrestricted coefficients of the matrix-logarithm parametrization of the underlying positive-definite matrix.

**Usage**

```
pdLogChol(value, form, nam, data)
```

**Arguments**

<code>value</code>	an optional initialization value, which can be any of the following: a <code>pdMat</code> object, a positive-definite matrix, a one-sided linear formula (with variables separated by <code>+</code> ), a vector of character strings, or a numeric vector. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.
<code>form</code>	an optional one-sided linear formula specifying the row/column names for the matrix represented by <code>object</code> . Because factors may be present in <code>form</code> , the formula needs to be evaluated on a <code>data.frame</code> to resolve the names it defines. This argument is ignored when <code>value</code> is a one-sided formula. Defaults to <code>NULL</code> .
<code>nam</code>	an optional vector of character strings specifying the row/column names for the matrix represented by <code>object</code> . It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when <code>value</code> is a vector of character strings. Defaults to <code>NULL</code> .
<code>data</code>	an optional data frame in which to evaluate the variables named in <code>value</code> and <code>form</code> . It is used to obtain the levels for <code>factors</code> , which affect the dimensions and the row/column names of the underlying matrix. If <code>NULL</code> , no attempt is made to obtain information on <code>factors</code> appearing in the formulas. Defaults to the parent frame from which the function was called.

**Value**

a `pdLogChol` object representing a general positive-definite matrix, also inheriting from class `pdMat`.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

pdMat

*Positive-Definite Matrix*

---

**Description**

This function gives an alternative way of constructing an object inheriting from the `pdMat` class named in `pdClass`, or from `data.class(object)` if `object` inherits from `pdMat`, and is mostly used internally in other functions. See the documentation on the principal constructor function, generally with the same name as the `pdMat` class of object.

**Usage**

```
pdMat(value, form, nam, data, pdClass)
```

**Arguments**

<code>value</code>	an optional initialization value, which can be any of the following: a <code>pdMat</code> object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.
<code>form</code>	an optional one-sided linear formula specifying the row/column names for the matrix represented by <code>object</code> . Because factors may be present in <code>form</code> , the formula needs to be evaluated on a <code>data.frame</code> to resolve the names it defines. This argument is ignored when <code>value</code> is a one-sided formula. Defaults to <code>NULL</code> .

nam	an optional vector of character strings specifying the row/column names for the matrix represented by object. It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when value is a vector of character strings. Defaults to NULL.
data	an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.
pdClass	an optional character string naming the pdMat class to be assigned to the returned object. This argument will only be used when value is not a pdMat object. Defaults to "pdSymm".

**Value**

a pdMat object representing a positive-definite matrix, inheriting from the class named in pdClass, or from class(object), if object inherits from pdMat.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

pd1
```

---

pdMatrix

*Extract Matrix or Square-Root Factor from a pdMat Object*

---

**Description**

The positive-definite matrix represented by object, or a square-root factor of it is obtained. Letting  $\Sigma$  denote a positive-definite matrix, a square-root factor of  $\Sigma$  is any square matrix  $L$  such that  $\Sigma = L'L$ . This function extracts  $S$  or  $L$ .

**Usage**

```
pdMatrix(object, factor)
```

**Arguments**

`object` an object inheriting from class `pdMat`, representing a positive definite matrix.

`factor` an optional logical value. If `TRUE`, a square-root factor of the positive-definite matrix represented by `object` is returned; else, if `FALSE`, the positive-definite matrix is returned. Defaults to `FALSE`.

**Value**

if `fact` is `FALSE` the positive-definite matrix represented by `object` is returned; else a square-root of the positive-definite matrix is returned.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

`pdMatrix.reStruct` *Extract Matrix or Square-Root Factor from Components of an reStruct Object*

---

**Description**

This method function extracts the positive-definite matrices corresponding to the `pdMat` elements of `object`, or square-root factors of the positive-definite matrices.

**Usage**

```
## S3 method for class 'reStruct':
pdMatrix(object, factor)
```

**Arguments**

`object` an object inheriting from class `reStruct`, representing a random effects structure and consisting of a list of `pdMat` objects.

`factor` an optional logical value. If `TRUE`, square-root factors of the positive-definite matrices represented by the elements of `object` are returned; else, if `FALSE`, the positive-definite matrices are returned. Defaults to `FALSE`.

**Value**

a list with components given by the positive-definite matrices corresponding to the elements of `object`, or square-root factors of the positive-definite matrices.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

pdNatural

*General Positive-Definite Matrix in Natural Parametrization*

---

**Description**

This function is a constructor for the `pdNatural` class, representing a general positive-definite matrix, using a natural parametrization. If the matrix associated with `object` is of dimension  $n$ , it is represented by  $n(n+1)/2$  parameters. Letting  $\sigma_{ij}$  denote the  $ij$ -th element of the underlying positive definite matrix and  $\rho_{ij} = \sigma_{ij} / \sqrt{\sigma_{ii}\sigma_{jj}}$ ,  $i \neq j$  denote the associated "correlations", the "natural" parameters are given by  $\sqrt{\sigma_{ii}}$ ,  $i = 1, \dots, n$  and  $\log((1 + \rho_{ij}) / (1 - \rho_{ij}))$ ,  $i \neq j$ . Note that all natural parameters are individually unrestricted, but not jointly unrestricted (meaning that not all unrestricted vectors would give positive-definite matrices). Therefore, this parametrization should NOT be used for optimization. It is mostly used for deriving approximate confidence intervals on parameters following the optimization of an objective function. When `value` is `numeric(0)`, an uninitialized `pdMat` object, a one-sided formula, or a vector of character strings, `object` is returned as an uninitialized `pdSymm` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is an initialized `pdMat` object, `object` will be constructed from `as.matrix(value)`. Finally, if `value` is a numeric vector, it is assumed to represent the natural parameters of the underlying positive-definite matrix.

**Usage**

```
pdNatural(value, form, nam, data)
```

**Arguments**

value	an optional initialization value, which can be any of the following: a <code>pdMat</code> object, a positive-definite matrix, a one-sided linear formula (with variables separated by <code>+</code> ), a vector of character strings, or a numeric vector. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.
form	an optional one-sided linear formula specifying the row/column names for the matrix represented by <code>object</code> . Because factors may be present in <code>form</code> , the formula needs to be evaluated on a <code>data.frame</code> to resolve the names it defines. This argument is ignored when <code>value</code> is a one-sided formula. Defaults to <code>NULL</code> .
nam	an optional vector of character strings specifying the row/column names for the matrix represented by <code>object</code> . It must have length equal to the dimension of the underlying positive-definite matrix and unrepliated elements. This argument is ignored when <code>value</code> is a vector of character strings. Defaults to <code>NULL</code> .
data	an optional data frame in which to evaluate the variables named in <code>value</code> and <code>form</code> . It is used to obtain the levels for <code>factors</code> , which affect the dimensions and the row/column names of the underlying matrix. If <code>NULL</code> , no attempt is made to obtain information on <code>factors</code> appearing in the formulas. Defaults to the parent frame from which the function was called.

**Value**

a `pdNatural` object representing a general positive-definite matrix in natural parametrization, also inheriting from class `pdMat`.

`pdSymm`*General Positive-Definite Matrix*

---

**Description**

This function is a constructor for the `pdSymm` class, representing a general positive-definite matrix. If the matrix associated with `object` is of dimension  $n$ , it is represented by  $n(n+1)/2$  unrestricted parameters, using the matrix-logarithm parametrization described in Pinheiro and Bates (1996). When `value` is `numeric(0)`, an uninitialized `pdMat` object, a one-sided formula, or a vector of character strings, `object` is returned as an uninitialized `pdSymm` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is an initialized `pdMat` object, `object` will be constructed from `as.matrix(value)`. Finally, if `value` is a numeric vector, it is assumed to represent the unrestricted coefficients of the matrix-logarithm parametrization of the underlying positive-definite matrix.

**Usage**

```
pdSymm(value, form, nam, data)
```

**Arguments**

<code>value</code>	an optional initialization value, which can be any of the following: a <code>pdMat</code> object, a positive-definite matrix, a one-sided linear formula (with variables separated by <code>+</code> ), a vector of character strings, or a numeric vector. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.
<code>form</code>	an optional one-sided linear formula specifying the row/column names for the matrix represented by <code>object</code> . Because factors may be present in <code>form</code> , the formula needs to be evaluated on a <code>data.frame</code> to resolve the names it defines. This argument is ignored when <code>value</code> is a one-sided formula. Defaults to <code>NULL</code> .
<code>nam</code>	an optional vector of character strings specifying the row/column names for the matrix represented by <code>object</code> . It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when <code>value</code> is a vector of character strings. Defaults to <code>NULL</code> .
<code>data</code>	an optional data frame in which to evaluate the variables named in <code>value</code> and <code>form</code> . It is used to obtain the levels for <code>factors</code> , which affect the dimensions and the row/column names of the underlying matrix. If <code>NULL</code> , no attempt is made to obtain information on <code>factors</code> appearing in the formulas. Defaults to the parent frame from which the function was called.

**Value**

a `pdSymm` object representing a general positive-definite matrix, also inheriting from class `pdMat`.

Phenobarb

*Phenobarbital Kinetics*

---

## Description

The `Phenobarb` data frame has 744 rows and 7 columns.

## Format

This data frame contains the following columns:

**Subject** an ordered factor identifying the infant.

**Wt** a numeric vector giving the birth weight of the infant (kg).

**Apgar** an ordered factor giving the 5-minute Apgar score for the infant. This is an indication of health of the newborn infant.

**ApgarInd** a factor indicating whether the 5-minute Apgar score is  $< 5$  or  $\geq 5$ .

**time** a numeric vector giving the time when the sample is drawn or drug administered (hr).

**dose** a numeric vector giving the dose of drug administered (*ug/kg*).

**conc** a numeric vector giving the phenobarbital concentration in the serum (*ug/L*).

## Details

Data from a pharmacokinetics study of phenobarbital in neonatal infants. During the first few days of life the infants receive multiple doses of phenobarbital for prevention of seizures. At irregular intervals blood samples are drawn and serum phenobarbital concentrations are determined. The data were originally given in Grasela and Donn(1985) and are analyzed in Boeckmann, Sheiner and Beal (1994), in Davidian and Giltinan (1995), and in Littell et al. (1996).

 phenoModel

---

*Model function for the Phenobarb data*

---

**Description**

A model function for a model used with the Phenobarb data. This function uses compiled C code to improve execution speed.

**Usage**

```
phenoModel(Subject, time, dose, lCl, lV)
```

**Arguments**

Subject	an integer vector of subject identifiers. These should be sorted in increasing order.
time	numeric. A vector of the times at which the sample was drawn or the drug administered (hr).
dose	numeric. A vector of doses of drug administered (ug/kg).
lCl	numeric. A vector of values of the natural log of the clearance parameter according to Subject and time.
lV	numeric. A vector of values of the natural log of the effective volume of distribution according to Subject and time.

**Details**

See the details section of [Phenobarb](#) for a description of the model function that phenoModel evaluates.

**Value**

a numeric vector of predicted phenobarbital concentrations.

---

Pixel	<i>X-ray pixel intensities over time</i>
-------	--

---

## Description

The `Pixel` data frame has 102 rows and 4 columns of data on the pixel intensities of CT scans of dogs over time

## Format

This data frame contains the following columns:

**Dog** a factor with levels 1 to 10 designating the dog on which the scan was made

**Side** a factor with levels L and R designating the side of the dog being scanned

**day** a numeric vector giving the day post injection of the contrast on which the scan was made

**pixel** a numeric vector of pixel intensities

## Source

## Examples

```
fml <- lme(pixel ~ day + I(day^2), data = Pixel,
          random = list(Dog = ~ day, Side = ~ 1))
summary(fml)
VarCorr(fml)
```

---

plot.ACF	<i>Plot an ACF Object</i>
----------	---------------------------

---

## Description

an `xyplot` of the autocorrelations versus the lags, with `type = "h"`, is produced. If `alpha > 0`, curves representing the critical limits for a two-sided test of level `alpha` for the autocorrelations are added to the plot.

## Usage

```
## S3 method for class 'ACF':
plot(x, alpha, xlab, ylab, grid, ...)
```

**Arguments**

x	an object inheriting from class <code>ACF</code> , consisting of a data frame with two columns named <code>lag</code> and <code>ACF</code> , representing the autocorrelation values and the corresponding lags.
alpha	an optional numeric value with the significance level for testing if the autocorrelations are zero. Lines corresponding to the lower and upper critical values for a test of level <code>alpha</code> are added to the plot. Default is 0, in which case no lines are plotted.
xlab, ylab	optional character strings with the x- and y-axis labels. Default respectively to "Lag" and "Autocorrelation".
grid	an optional logical value indicating whether a grid should be added to plot. Default is <code>FALSE</code> .
...	optional arguments passed to the <code>xyplot</code> function.

**Value**

an `xyplot` Trellis plot.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[ACF](#), [xyplot](#)

**Examples**

```
fml <- lme(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary)
plot(ACF(fml, maxLag = 10), alpha = 0.01)
```

---

plot.augPred

*Plot an augPred Object*

---

**Description**

A Trellis `xyplot` of predictions versus the primary covariate is generated, with a different panel for each value of the grouping factor. Predicted values are joined by lines, with different line types (colors) being used for each level of grouping. Original observations are represented by circles.

**Usage**

```
## S3 method for class 'augPred':
plot(x, key, grid, ...)
```

**Arguments**

<code>x</code>	an object of class <code>augPred</code> .
<code>key</code>	an optional logical value, or list. If <code>TRUE</code> , a legend is included at the top of the plot indicating which symbols (colors) correspond to which prediction levels. If <code>FALSE</code> , no legend is included. If given as a list, <code>key</code> is passed down as an argument to the <code>trellis</code> function generating the plots ( <code>xyplot</code> ). Defaults to <code>TRUE</code> .
<code>grid</code>	an optional logical value indicating whether a grid should be added to plot. Default is <code>FALSE</code> .
<code>...</code>	optional arguments passed down to the <code>trellis</code> function generating the plots.

**Value**

A Trellis plot of predictions versus the primary covariate, with panels determined by the grouping factor.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

**Examples**

```
fml <- lme(Orthodont)
plot(augPred(fml, level = 0:1, length.out = 2))
```

---

`plot.compareFits` *Plot a compareFits Object*

---

**Description**

A Trellis `dotplot` of the values being compared, with different rows per group, is generated, with a different panel for each coefficient. Different symbols (colors) are used for each object being compared.

**Usage**

```
## S3 method for class 'compareFits':
plot(x, subset, key, mark, ...)
```

**Arguments**

<code>x</code>	an object of class <code>compareFits</code> .
<code>subset</code>	an optional logical or integer vector specifying which rows of <code>x</code> should be used in the plots. If missing, all rows are used.
<code>key</code>	an optional logical value, or list. If <code>TRUE</code> , a legend is included at the top of the plot indicating which symbols (colors) correspond to which objects being compared. If <code>FALSE</code> , no legend is included. If given as a list, <code>key</code> is passed down as an argument to the <code>trellis</code> function generating the plots ( <code>dotplot</code> ). Defaults to <code>TRUE</code> .
<code>mark</code>	an optional numeric vector, of length equal to the number of coefficients being compared, indicating where vertical lines should be drawn in the plots. If missing, no lines are drawn.
<code>...</code>	optional arguments passed down to the <code>trellis</code> function generating the plots.

**Value**

A Trellis `dotplot` of the values being compared, with rows determined by the groups and panels by the coefficients.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[compareFits](#), [pairs.compareFits](#), [dotplot](#)

**Examples**

```
## Not run:
fm1 <- lmList(Orthodont)
fm2 <- lme(Orthodont)
plot(compareFits(coef(fm1), coef(fm2)))

## End(Not run)
```

---

plot.gls

*Plot a gls Object*

---

**Description**

Diagnostic plots for the linear model fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. If `form` is a one-sided formula, histograms of the variable on the right hand side of the formula, before a `|` operator, are displayed (the Trellis function `histogram` is used). If `form` is two-sided and both its left and right hand side variables are numeric, scatter plots are displayed (the Trellis function `xyplot` is used). Finally, if `form` is two-sided and its left hand side variable is a factor, box-plots of the right hand side variable by the levels of the left hand side variable are displayed (the Trellis function `bwplot` is used).

**Usage**

```
## S3 method for class 'glms':
plot(x, form, abline, id, idLabels, idResType, grid, ...)
```

**Arguments**

<code>x</code>	an object inheriting from class <code>glms</code> , representing a generalized least squares fitted linear model.
<code>form</code>	an optional formula specifying the desired type of plot. Any variable present in the original data frame used to obtain <code>x</code> can be referenced. In addition, <code>x</code> itself can be referenced in the formula using the symbol <code>"."</code> . Conditional expressions on the right of a <code> </code> operator can be used to define separate panels in a Trellis display. Default is <code>resid(., type = "p") ~ fitted(.)</code> , corresponding to a plot of the standardized residuals versus fitted values, both evaluated at the innermost level of nesting.
<code>abline</code>	an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.
<code>id</code>	an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals. Observations with absolute standardized residuals greater than the $1 - value/2$ quantile of the standard normal distribution are identified in the plot using <code>idLabels</code> . If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.
<code>idLabels</code>	an optional vector, or one-sided formula. If given as a vector, it is converted to character mode and used to label the observations identified according to <code>id</code> . If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character mode and used to label the identified observations. Default is the innermost grouping factor.
<code>idResType</code>	an optional character string specifying the type of residuals to be used in identifying outliers, when <code>id</code> is a numeric value. If <code>"pearson"</code> , the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if <code>"normalized"</code> , the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to <code>"pearson"</code> .
<code>grid</code>	an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if <code>xyplot</code> defaults to <code>TRUE</code> , else defaults to <code>FALSE</code> .
<code>...</code>	optional arguments passed to the Trellis plot function.

**Value**

a diagnostic Trellis plot.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[gls](#), [xyplot](#), [bwplot](#), [histogram](#)

          correlation = corAR1(form = ~ 1 | Mare))
# standardized residuals versus fitted values by Mare
plot(fm1, resid(., type = "p") ~ fitted(.) | Mare, abline = 0)
# box-plots of residuals by Mare
plot(fm1, Mare ~ resid(.))
# observed versus fitted values by Mare
plot(fm1, follicles ~ fitted(.) | Mare, abline = c(0,1))
```

---

```
plot.intervals.lmList
```

*Plot lmList Confidence Intervals*

---

**Description**

A Trellis dot-plot of the confidence intervals on the linear model coefficients is generated, with a different panel for each coefficient. Rows in the dot-plot correspond to the names of the `lm` components of the `lmList` object used to produce `x`. The lower and upper confidence limits are connected by a line segment and the estimated coefficients are marked with a "+". The Trellis function `dotplot` is used in this method function.

**Usage**

```
## S3 method for class 'intervals.lmList':
plot(x, ...)
```

**Arguments**

`x` an object inheriting from class `intervals.lmList`, representing confidence intervals and estimates for the coefficients in the `lm` components of the `lmList` object used to produce `x`.

`...` optional arguments passed to the Trellis `dotplot` function.

**Value**

a Trellis plot with the confidence intervals on the coefficients of the individual `lm` components of the `lmList` that generated `x`.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

**Examples**

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
plot(intervals(fm1))
```

plot.lme

*Plot an lme or nls object***Description**

Diagnostic plots for the linear mixed-effects fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. If `form` is a one-sided formula, histograms of the variable on the right hand side of the formula, before a `|` operator, are displayed (the Trellis function `histogram` is used). If `form` is two-sided and both its left and right hand side variables are numeric, scatter plots are displayed (the Trellis function `xyplot` is used). Finally, if `form` is two-sided and its left hand side variable is a factor, box-plots of the right hand side variable by the levels of the left hand side variable are displayed (the Trellis function `bwplot` is used).

**Usage**

```
## S3 method for class 'lme':
plot(x, form, abline, id, idLabels, idResType, grid, ...)
## S3 method for class 'nls':
plot(x, form, abline, id, idLabels, idResType, grid, ...)
```

**Arguments**

- |                     |   |
|---------------------|---|
| <code>x</code>      | an object inheriting from class <code>lme</code> , representing a fitted linear mixed-effects model, or from <code>nls</code> , representing an fitted nonlinear least squares model.   |
| <code>form</code>   | an optional formula specifying the desired type of plot. Any variable present in the original data frame used to obtain <code>x</code> can be referenced. In addition, <code>x</code> itself can be referenced in the formula using the symbol <code>". "</code> . Conditional expressions on the right of a <code> </code> operator can be used to define separate panels in a Trellis display. Default is <code>resid(., type = "p") ~ fitted(.)</code> , corresponding to a plot of the standardized residuals versus fitted values, both evaluated at the innermost level of nesting.                     |
| <code>abline</code> | an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.  |
| <code>id</code>     | an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized, or normalized residuals. Observations with absolute standardized (normalized) residuals greater than the $1 - \text{value}/2$ quantile of the standard normal distribution are identified in the plot using <code>idLabels</code> . If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified. |

<code>idLabels</code>	an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to <code>id</code> . If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is the innermost grouping factor.
<code>idResType</code>	an optional character string specifying the type of residuals to be used in identifying outliers, when <code>id</code> is a numeric value. If "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".
<code>grid</code>	an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if <code>xyplot</code> defaults to TRUE, else defaults to FALSE.
<code>...</code>	optional arguments passed to the Trellis plot function.

**Value**

a diagnostic Trellis plot.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

# box-plots of residuals by Subject
plot(fml, Subject ~ resid(.))
# observed versus fitted values by Subject
plot(fml, distance ~ fitted(.) | Subject, abline = c(0,1))
```

---

plot.lmList

*Plot an lmList Object*

---

**Description**

Diagnostic plots for the linear model fits corresponding to the  $x$  components are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. If `form` is a one-sided formula, histograms of the variable on the right hand side of the formula, before a `|` operator, are displayed (the Trellis function `histogram` is used). If `form` is two-sided and both its left and right hand side

variables are numeric, scatter plots are displayed (the Trellis function `xyplot` is used). Finally, if `form` is two-sided and its left hand side variable is a factor, box-plots of the right hand side variable by the levels of the left hand side variable are displayed (the Trellis function `bwplot` is used).

### Usage

```
## S3 method for class 'lmList':
plot(x, form, abline, id, idLabels, grid, ...)
```

### Arguments

<code>x</code>	an object inheriting from class <code>lmList</code> , representing a list of <code>lm</code> objects with a common model.
<code>form</code>	an optional formula specifying the desired type of plot. Any variable present in the original data frame used to obtain <code>x</code> can be referenced. In addition, <code>x</code> itself can be referenced in the formula using the symbol <code>"."</code> . Conditional expressions on the right of a <code> </code> operator can be used to define separate panels in a Trellis display. Default is <code>resid(., type = "pool") ~ fitted(.)</code> , corresponding to a plot of the standardized residuals (using a pooled estimate for the residual standard error) versus fitted values.
<code>abline</code>	an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.
<code>id</code>	an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals. Observations with absolute standardized residuals greater than the $1 - value/2$ quantile of the standard normal distribution are identified in the plot using <code>idLabels</code> . If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.
<code>idLabels</code>	an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to <code>id</code> . If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is <code>getGroups(x)</code> .
<code>grid</code>	an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if <code>xyplot</code> defaults to <code>TRUE</code> , else defaults to <code>FALSE</code> .
<code>...</code>	optional arguments passed to the Trellis plot function.

### Value

a diagnostic Trellis plot.

**Examples**

```
fml <- lmList(distance ~ age | Subject, Orthodont)
# standardized residuals versus fitted values by gender
plot(fml, resid(., type = "pool") ~ fitted(.) | Sex, abline = 0, id = 0.05)
# box-plots of residuals by Subject
plot(fml, Subject ~ resid(.))
# observed versus fitted values by Subject
plot(fml, distance ~ fitted(.) | Subject, abline = c(0,1))
```

---

```
plot.nffGroupedData
```

*Plot an nffGroupedData Object*

---

**Description**

A Trellis dot-plot of the response by group is generated. If outer variables are specified, the combination of their levels are used to determine the panels of the Trellis display. The Trellis function `dotplot` is used.

**Usage**

```
## S3 method for class 'nffGroupedData':
plot(x, outer, inner, innerGroups, xlab, ylab, strip, panel, key,
      grid, ...)
```

**Arguments**

<code>x</code>	an object inheriting from class <code>nffGroupedData</code> , representing a <code>groupedData</code> object with a factor primary covariate and a single grouping level.
<code>outer</code>	an optional logical value or one-sided formula, indicating covariates that are outer to the grouping factor, which are used to determine the panels of the Trellis plot. If equal to <code>TRUE</code> , <code>attr(object, "outer")</code> is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to <code>NULL</code> , meaning that no outer covariates are to be used.
<code>inner</code>	an optional logical value or one-sided formula, indicating a covariate that is inner to the grouping factor, which is used to associate points within each panel of the Trellis plot. If equal to <code>TRUE</code> , <code>attr(object, "inner")</code> is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to <code>NULL</code> , meaning that no inner covariate is present.
<code>innerGroups</code>	an optional one-sided formula specifying a factor to be used for grouping the levels of the inner covariate. Different colors, or symbols, are used for each level of the <code>innerGroups</code> factor. Default is <code>NULL</code> , meaning that no <code>innerGroups</code> covariate is present.

<code>xlab</code>	an optional character string with the label for the horizontal axis. Default is the <code>y</code> elements of <code>attr(object, "labels")</code> and <code>attr(object, "units")</code> pasted together.
<code>ylab</code>	an optional character string with the label for the vertical axis. Default is the grouping factor name.
<code>strip</code>	an optional function passed as the <code>strip</code> argument to the <code>dotplot</code> function. Default is <code>strip.default(..., style = 1)</code> (see <code>trellis.args</code> ).
<code>panel</code>	an optional function used to generate the individual panels in the Trellis display, passed as the <code>panel</code> argument to the <code>dotplot</code> function.
<code>key</code>	an optional logical function or function. If <code>TRUE</code> and either <code>inner</code> or <code>innerGroups</code> are non-NULL, a legend for the different inner ( <code>innerGroups</code> ) levels is included at the top of the plot. If given as a function, it is passed as the <code>key</code> argument to the <code>dotplot</code> function. Default is <code>TRUE</code> is either <code>inner</code> or <code>innerGroups</code> are non-NULL and <code>FALSE</code> otherwise.
<code>grid</code>	this argument is included for consistency with the <code>plot.nfnGroupedData</code> method calling sequence. It is ignored in this method function.
<code>...</code>	optional arguments passed to the <code>dotplot</code> function.

**Value**

a Trellis dot-plot of the response by group.

*Plot an nfnGroupedData Object*

---

### Description

A Trellis plot of the response versus the primary covariate is generated. If outer variables are specified, the combination of their levels are used to determine the panels of the Trellis display. Otherwise, the levels of the grouping variable determine the panels. A scatter plot of the response versus the primary covariate is displayed in each panel, with observations corresponding to same inner group joined by line segments. The Trellis function `xyplot` is used.

### Usage

```
## S3 method for class 'nfnGroupedData':
plot(x, outer, inner, innerGroups, xlab, ylab, strip, aspect, panel,
      key, grid, ...)
```

### Arguments

<code>x</code>	an object inheriting from class <code>nfnGroupedData</code> , representing a <code>groupedData</code> object with a numeric primary covariate and a single grouping level.
<code>outer</code>	an optional logical value or one-sided formula, indicating covariates that are outer to the grouping factor, which are used to determine the panels of the Trellis plot. If equal to <code>TRUE</code> , <code>attr(object, "outer")</code> is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to <code>NULL</code> , meaning that no outer covariates are to be used.
<code>inner</code>	an optional logical value or one-sided formula, indicating a covariate that is inner to the grouping factor, which is used to associate points within each panel of the Trellis plot. If equal to <code>TRUE</code> , <code>attr(object, "inner")</code> is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to <code>NULL</code> , meaning that no inner covariate is present.
<code>innerGroups</code>	an optional one-sided formula specifying a factor to be used for grouping the levels of the <code>inner</code> covariate. Different colors, or line types, are used for each level of the <code>innerGroups</code> factor. Default is <code>NULL</code> , meaning that no <code>innerGroups</code> covariate is present.
<code>xlab, ylab</code>	optional character strings with the labels for the plot. Default is the corresponding elements of <code>attr(object, "labels")</code> and <code>attr(object, "units")</code> pasted together.
<code>strip</code>	an optional function passed as the <code>strip</code> argument to the <code>xyplot</code> function. Default is <code>strip.default(..., style = 1)</code> (see <code>trellis.args</code> ).
<code>aspect</code>	an optional character string indicating the aspect ratio for the plot passed as the <code>aspect</code> argument to the <code>xyplot</code> function. Default is <code>"xy"</code> (see <code>trellis.args</code> ).

panel	an optional function used to generate the individual panels in the Trellis display, passed as the <code>panel</code> argument to the <code>xyplot</code> function.
key	an optional logical function or function. If <code>TRUE</code> and <code>innerGroups</code> is non-NULL, a legend for the different <code>innerGroups</code> levels is included at the top of the plot. If given as a function, it is passed as the <code>key</code> argument to the <code>xyplot</code> function. Default is <code>TRUE</code> if <code>innerGroups</code> is non-NULL and <code>FALSE</code> otherwise.
grid	an optional logical value indicating whether a grid should be added to plot. Default is <code>TRUE</code> .
...	optional arguments passed to the <code>xyplot</code> function.

**Value**

a Trellis plot of the response versus the primary covariate.

`plot.nmGroupedData` *Plot an nmGroupedData Object*

---

**Description**

The `groupedData` object is summarized by the values of the `displayLevel` grouping factor (or the combination of its values and the values of the covariate indicated in `preserve`, if any is present). The collapsed data is used to produce a new `groupedData` object, with grouping factor given by the `displayLevel` factor, which is plotted using the appropriate `plot` method for `groupedData` objects with single level of grouping.

**Usage**

```
## S3 method for class 'nmGroupedData':
plot(x, collapseLevel, displayLevel, outer, inner,
     preserve, FUN, subset, key, grid, ...)
```

**Arguments**

- x** an object inheriting from class `nmGroupedData`, representing a `groupedData` object with multiple grouping factors.
- collapseLevel** an optional positive integer or character string indicating the grouping level to use when collapsing the data. Level values increase from outermost to innermost grouping. Default is the highest or innermost level of grouping.
- displayLevel** an optional positive integer or character string indicating the grouping level to use for determining the panels in the Trellis display, when `outer` is missing. Default is `collapseLevel`.
- outer** an optional logical value or one-sided formula, indicating covariates that are outer to the `displayLevel` grouping factor, which are used to determine the panels of the Trellis plot. If equal to `TRUE`, the `displayLevel` element `attr(object, "outer")` is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to `NULL`, meaning that no outer covariates are to be used.
- inner** an optional logical value or one-sided formula, indicating a covariate that is inner to the `displayLevel` grouping factor, which is used to associate points within each panel of the Trellis plot. If equal to `TRUE`, `attr(object, "outer")` is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to `NULL`, meaning that no inner covariate is present.
- preserve** an optional one-sided formula indicating a covariate whose levels should be preserved when collapsing the data according to the `collapseLevel` grouping factor. The collapsing factor is obtained by pasting together the levels of the `collapseLevel` grouping factor and the values of the covariate to be preserved. Default is `NULL`, meaning that no covariates need to be preserved.
- FUN** an optional summary function or a list of summary functions to be used for collapsing the data. The function or functions are applied only to variables in `object` that vary within the groups defined by `collapseLevel`. Invariant variables are always summarized by group using the unique value that they assume within that group. If `FUN` is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If `FUN` is a list of functions, the names in the list should designate classes of variables in the data such as `ordered`, `factor`, or `numeric`. The indicated function will be applied to any non-invariant variables of that class. The default functions to be used are `mean` for numeric factors, and `Mode` for both `factor` and `ordered`. The `Mode` function, defined internally in `gsummary`, returns the modal or most popular value of the variable. It is different from the `mode` function that returns the S-language mode of the variable.
- subset** an optional named list. Names can be either positive integers representing grouping levels, or names of grouping factors. Each element in the list is a vector indicating the levels of the corresponding grouping factor to be used for plotting the data. Default is `NULL`, meaning that all levels are used.
- key** an optional logical value, or list. If `TRUE`, a legend is included at the top of the plot indicating which symbols (colors) correspond to which prediction levels. If `FALSE`, no legend is included. If given as a list, `key` is passed down as an

	argument to the <code>trellis</code> function generating the plots ( <code>xyplot</code> ). Defaults to <code>TRUE</code> .
<code>grid</code>	an optional logical value indicating whether a grid should be added to plot. Default is <code>TRUE</code> .
<code>...</code>	optional arguments passed to the Trellis plot function.

**Value**

a Trellis display of the data collapsed over the values of the `collapseLevel` grouping factor and grouped according to the `displayLevel` grouping factor.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

```

---

`plot.ranef.lme`      *Plot a ranef.lme Object*

---

**Description**

If `form` is missing, or is given as a one-sided formula, a Trellis dot-plot of the random effects is generated, with a different panel for each random effect (coefficient). Rows in the dot-plot are determined by the `form` argument (if not missing) or by the row names of the random effects (coefficients). If a single factor is specified in `form`, its levels determine the dot-plot rows (with possibly multiple dots per row); otherwise, if `form` specifies a crossing of factors, the dot-plot rows are determined by all combinations of the levels of the individual factors in the formula. The Trellis function `dotplot` is used in this method function.

If `form` is a two-sided formula, a Trellis display is generated, with a different panel for each variable listed in the right hand side of `form`. Scatter plots are generated for numeric variables and boxplots are generated for categorical (`factor` or `ordered`) variables.

**Usage**

```
## S3 method for class 'ranef.lme':
plot(x, form, omitFixed, level, grid, control, ...)
```

**Arguments**

**x** an object inheriting from class `ranef.lme`, representing the estimated coefficients or estimated random effects for the `lme` object from which it was produced.

**form** an optional formula specifying the desired type of plot. If given as a one-sided formula, a `dotplot` of the estimated random effects (coefficients) grouped according to all combinations of the levels of the factors named in `form` is returned. Single factors (`~g`) or crossed factors (`~g1*g2`) are allowed. If given as a two-sided formula, the left hand side must be a single random effects (coefficient) and the right hand side is formed by covariates in `x` separated by `+`. A Trellis display of the random effect (coefficient) versus the named covariates is returned in this case. Default is `NULL`, in which case the row names of the random effects (coefficients) are used.

**omitFixed** an optional logical value indicating whether columns with values that are constant across groups should be omitted. Default is `TRUE`.

**level** an optional integer value giving the level of grouping to be used for `x`. Only used when `x` is a list with different components for each grouping level. Defaults to the highest or innermost level of grouping.

**grid** an optional logical value indicating whether a grid should be added to plot. Only applies to plots associated with two-sided formulas in `form`. Default is `FALSE`.

**control** an optional list with control values for the plot, when `form` is given as a two-sided formula. The control values are referenced by name in the `control` list and only the ones to be modified from the default need to be specified. Available values include: `drawLine`, a logical value indicating whether a loess smoother should be added to the scatter plots and a line connecting the medians should be added to the boxplots (default is `TRUE`); `span.loess`, used as the `span` argument in the call to `panel.loess` (default is `2/3`); `degree.loess`, used as the `degree` argument in the call to `panel.loess` (default is `1`); `cex.axis`, the character expansion factor for the x-axis (default is `0.8`); `srt.axis`, the rotation factor for the x-axis (default is `0`); and `mgp.axis`, the margin parameters for the x-axis (default is `c(2, 0.5, 0)`).

**...** optional arguments passed to the Trellis `dotplot` function.

**Value**

a Trellis plot of the estimated random-effects (coefficients) versus covariates, or groups.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

## End(Not run)
```

---

plot.ranef.lmList *Plot a ranef.lmList Object*

---

**Description**

If `form` is missing, or is given as a one-sided formula, a Trellis dot-plot of the random effects is generated, with a different panel for each random effect (coefficient). Rows in the dot-plot are determined by the `form` argument (if not missing) or by the row names of the random effects (coefficients). If a single factor is specified in `form`, its levels determine the dot-plot rows (with possibly multiple dots per row); otherwise, if `form` specifies a crossing of factors, the dot-plot rows are determined by all combinations of the levels of the individual factors in the formula. The Trellis function `dotplot` is used in this method function.

If `form` is a two-sided formula, a Trellis display is generated, with a different panel for each variable listed in the right hand side of `form`. Scatter plots are generated for numeric variables and boxplots are generated for categorical (`factor` or `ordered`) variables.

**Usage**

```
## S3 method for class 'ranef.lmList':
plot(x, form, grid, control, ...)
```

**Arguments**

- |                      |  |
|----------------------|--|
| <code>x</code>       | an object inheriting from class <code>ranef.lmList</code> , representing the estimated coefficients or estimated random effects for the <code>lmList</code> object from which it was produced.   |
| <code>form</code>    | an optional formula specifying the desired type of plot. If given as a one-sided formula, a <code>dotplot</code> of the estimated random effects (coefficients) grouped according to all combinations of the levels of the factors named in <code>form</code> is returned. Single factors ( <code>~g</code> ) or crossed factors ( <code>~g1*g2</code> ) are allowed. If given as a two-sided formula, the left hand side must be a single random effects (coefficient) and the right hand side is formed by covariates in <code>x</code> separated by <code>+</code> . A Trellis display of the random effect (coefficient) versus the named covariates is returned in this case. Default is <code>NULL</code> , in which case the row names of the random effects (coefficients) are used. |
| <code>grid</code>    | an optional logical value indicating whether a grid should be added to plot. Only applies to plots associated with two-sided formulas in <code>form</code> . Default is <code>FALSE</code> .   |
| <code>control</code> | an optional list with control values for the plot, when <code>form</code> is given as a two-sided formula. The control values are referenced by name in the <code>control</code> list and only the ones to be modified from the default need to be specified.  |

Available values include: `drawLine`, a logical value indicating whether a loess smoother should be added to the scatter plots and a line connecting the medians should be added to the boxplots (default is `TRUE`); `span.loess`, used as the `span` argument in the call to `panel.loess` (default is `2/3`); `degree.loess`, used as the `degree` argument in the call to `panel.loess` (default is `1`); `cex.axis`, the character expansion factor for the x-axis (default is `0.8`); `srt.axis`, the rotation factor for the x-axis (default is `0`); and `mgp.axis`, the margin parameters for the x-axis (default is `c(2, 0.5, 0)`).

... optional arguments passed to the Trellis `dotplot` function.

### Value

a Trellis plot of the estimated random-effects (coefficients) versus covariates, or groups.

### Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

### See Also

[lmList](#), [dotplot](#)

### Examples

```
fml <- lmList(distance ~ age | Subject, Orthodont)
plot(ranef(fml))

plot(fmlRE, form = ~ Sex)
## Not run: plot(fmlRE, form = age ~ Sex)
```

---

plot.Variogram      *Plot a Variogram Object*

---

### Description

an xyplot of the semi-variogram versus the distances is produced. If `smooth = TRUE`, a loess smoother is added to the plot. If `showModel = TRUE` and `x` includes an "modelVariog" attribute, the corresponding semi-variogram is added to the plot.

### Usage

```
## S3 method for class 'Variogram':
plot(x, smooth, showModel, sigma, span, xlab,
     ylab, type, ylim, grid, ...)
```

**Arguments**

<code>x</code>	an object inheriting from class <code>Variogram</code> , consisting of a data frame with two columns named <code>variog</code> and <code>dist</code> , representing the semi-variogram values and the corresponding distances.
<code>smooth</code>	an optional logical value controlling whether a <code>loess</code> smoother should be added to the plot. Defaults to <code>TRUE</code> , when <code>showModel</code> is <code>FALSE</code> .
<code>showModel</code>	an optional logical value controlling whether the semi-variogram corresponding to an <code>"modelVariog"</code> attribute of <code>x</code> , if any is present, should be added to the plot. Defaults to <code>TRUE</code> , when the <code>"modelVariog"</code> attribute is present.
<code>sigma</code>	an optional numeric value used as the height of a horizontal line displayed in the plot. Can be used to represent the process standard deviation. Default is <code>NULL</code> , implying that no horizontal line is drawn.
<code>span</code>	an optional numeric value with the smoothing parameter for the <code>loess</code> fit. Default is 0.6.
<code>xlab, ylab</code>	optional character strings with the x- and y-axis labels. Default respectively to <code>"Distance"</code> and <code>"SemiVariogram"</code> .
<code>type</code>	an optional character indicating the type of plot. Defaults to <code>"p"</code> .
<code>ylim</code>	an optional numeric vector with the limits for the y-axis. Defaults to <code>c(0, max(x\$variog))</code> .
<code>grid</code>	an optional logical value indicating whether a grid should be added to plot. Default is <code>FALSE</code> .
<code>...</code>	optional arguments passed to the Trellis <code>xyplot</code> function.

**Value**

an `xyplot` Trellis plot.

```

---

pooledSD

*Extract Pooled Standard Deviation*

---

### Description

The pooled estimated standard deviation is obtained by adding together the residual sum of squares for each non-null element of `object`, dividing by the sum of the corresponding residual degrees-of-freedom, and taking the square-root.

### Usage

```
pooledSD(object)
```

### Arguments

`object` an object inheriting from class `lmList`.

### Value

the pooled standard deviation for the non-null elements of `object`, with an attribute `df` with the number of degrees-of-freedom used in the estimation.

### Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

pooledSD(fm1)
```

---

predict.gls

*Predictions from a gls Object*

---

### Description

The predictions for the linear model represented by `object` are obtained at the covariate values defined in `newdata`.

### Usage

```
## S3 method for class 'glms':
predict(object, newdata, na.action, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>gls</code> , representing a generalized least squares fitted linear model.
<code>newdata</code>	an optional data frame to be used for obtaining the predictions. All variables used in the linear model must be present in the data frame. If missing, the fitted values are returned.
<code>na.action</code>	a function that indicates what should happen when <code>newdata</code> contains NAs. The default action ( <code>na.fail</code> ) causes the function to print an error message and terminate if there are any incomplete observations.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with the predicted values.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates  
<bates@stat.wisc.edu>

**See Also**

predict(fml, newOvary)
```

---

predict.gnls

*Predictions from a gnls Object*

---

**Description**

The predictions for the nonlinear model represented by `object` are obtained at the covariate values defined in `newdata`.

**Usage**

```
## S3 method for class 'gnls':
predict(object, newdata, na.action, naPattern, ...)
```

**Arguments**

object	an object inheriting from class <code>gnls</code> , representing a generalized nonlinear least squares fitted model.
newdata	an optional data frame to be used for obtaining the predictions. All variables used in the nonlinear model must be present in the data frame. If missing, the fitted values are returned.
na.action	a function that indicates what should happen when <code>newdata</code> contains NAs. The default action ( <code>na.fail</code> ) causes the function to print an error message and terminate if there are any incomplete observations.
naPattern	an expression or formula object, specifying which returned values are to be regarded as missing.
...	some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with the predicted values.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[gnls](#)

**Examples**

```
fml <- gnls(weight ~ SSlogis(Time, Asym, xmid, scal), Soybean,
           weights = varPower())
newSoybean <- data.frame(Time = c(10, 30, 50, 80, 100))
predict(fml, newSoybean)
```

---

predict.lme

*Predictions from an lme Object*

---

**Description**

The predictions at level  $i$  are obtained by adding together the population predictions (based only on the fixed effects estimates) and the estimated contributions of the random effects to the predictions at grouping levels less or equal to  $i$ . The resulting values estimate the best linear unbiased predictions (BLUPs) at level  $i$ . If group values not included in the original grouping factors are present in `newdata`, the corresponding predictions will be set to NA for levels greater or equal to the level at which the unknown groups occur.

**Usage**

```
## S3 method for class 'lme':
predict(object, newdata, level, asList, na.action, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>lme</code> , representing a fitted linear mixed-effects model.
<code>newdata</code>	an optional data frame to be used for obtaining the predictions. All variables used in the fixed and random effects models, as well as the grouping factors, must be present in the data frame. If missing, the fitted values are returned.
<code>level</code>	an optional integer vector giving the level(s) of grouping to be used in obtaining the predictions. Level values increase from outermost to innermost grouping, with level zero corresponding to the population predictions. Defaults to the highest or innermost level of grouping.
<code>asList</code>	an optional logical value. If <code>TRUE</code> and a single value is given in <code>level</code> , the returned object is a list with the predictions split by groups; else the returned value is either a vector or a data frame, according to the length of <code>level</code> .
<code>na.action</code>	a function that indicates what should happen when <code>newdata</code> contains NAs. The default action ( <code>na.fail</code> ) causes the function to print an error message and terminate if there are any incomplete observations.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

if a single level of grouping is specified in `level`, the returned value is either a list with the predictions split by groups (`asList = TRUE`) or a vector with the predictions (`asList = FALSE`); else, when multiple grouping levels are specified in `level`, the returned object is a data frame with columns given by the predictions at different levels and the grouping factors.

**Examples**

```
fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
newOrth <- data.frame(Sex = c("Male", "Male", "Female", "Female", "Male", "Male"),
                    age = c(15, 20, 10, 12, 2, 4),
                    Subject = c("M01", "M01", "F30", "F30", "M04", "M04"))
predict(fm1, newOrth, level = 0:1)
```

---

predict.lmList      *Predictions from an lmList Object*

---

### Description

If the grouping factor corresponding to `object` is included in `newdata`, the data frame is partitioned according to the grouping factor levels; else, `newdata` is repeated for all `lm` components. The predictions and, optionally, the standard errors for the predictions, are obtained for each `lm` component of `object`, using the corresponding element of the partitioned `newdata`, and arranged into a list with as many components as `object`, or combined into a single vector or data frame (if `se.fit=TRUE`).

### Usage

```
## S3 method for class 'lmList':  
predict(object, newdata, subset, pool, asList, se.fit, ...)
```

### Arguments

<code>object</code>	an object inheriting from class <code>lmList</code> , representing a list of <code>lm</code> objects with a common model.
<code>newdata</code>	an optional data frame to be used for obtaining the predictions. All variables used in the <code>object</code> model formula must be present in the data frame. If missing, the same data frame used to produce <code>object</code> is used.
<code>subset</code>	an optional character or integer vector naming the <code>lm</code> components of <code>object</code> from which the predictions are to be extracted. Default is <code>NULL</code> , in which case all components are used.
<code>asList</code>	an optional logical value. If <code>TRUE</code> , the returned object is a list with the predictions split by groups; else the returned value is a vector. Defaults to <code>FALSE</code> .
<code>pool</code>	an optional logical value indicating whether a pooled estimate of the residual standard error should be used. Default is <code>attr(object, "pool")</code> .
<code>se.fit</code>	an optional logical value indicating whether pointwise standard errors should be computed along with the predictions. Default is <code>FALSE</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

### Value

a list with components given by the predictions (and, optionally, the standard errors for the predictions) from each `lm` component of `object`, a vector with the predictions from all `lm` components of `object`, or a data frame with columns given by the predictions and their corresponding standard errors.

fml <- lmList(distance ~ age | Subject, Orthodont)
predict(fml, se.fit = TRUE)
```

---

predict.nlme

*Predictions from an nlme Object*

---

**Description**

The predictions at level  $i$  are obtained by adding together the contributions from the estimated fixed effects and the estimated random effects at levels less or equal to  $i$  and evaluating the model function at the resulting estimated parameters. If group values not included in the original grouping factors are present in `newdata`, the corresponding predictions will be set to NA for levels greater or equal to the level at which the unknown groups occur.

**Usage**

```
## S3 method for class 'nlme':
predict(object, newdata, level, asList, na.action,
naPattern, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>nlme</code> , representing a fitted nonlinear mixed-effects model.
<code>newdata</code>	an optional data frame to be used for obtaining the predictions. All variables used in the nonlinear model, the fixed and the random effects models, as well as the grouping factors, must be present in the data frame. If missing, the fitted values are returned.
<code>level</code>	an optional integer vector giving the level(s) of grouping to be used in obtaining the predictions. Level values increase from outermost to innermost grouping, with level zero corresponding to the population predictions. Defaults to the highest or innermost level of grouping.
<code>asList</code>	an optional logical value. If <code>TRUE</code> and a single value is given in <code>level</code> , the returned object is a list with the predictions split by groups; else the returned value is either a vector or a data frame, according to the length of <code>level</code> .
<code>na.action</code>	a function that indicates what should happen when <code>newdata</code> contains NAs. The default action ( <code>na.fail</code> ) causes the function to print an error message and terminate if there are any incomplete observations.
<code>naPattern</code>	an expression or formula object, specifying which returned values are to be regarded as missing.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

if a single level of grouping is specified in `level`, the returned value is either a list with the predictions split by groups (`asList = TRUE`) or a vector with the predictions (`asList = FALSE`); else, when multiple grouping levels are specified in `level`, the returned object is a data frame with columns given by the predictions at different levels and the grouping factors.

```
fml <- nlme(height ~ SSasym(age, Asym, R0, lrc),
            data = Loblolly,
            fixed = Asym + R0 + lrc ~ 1,
            random = Asym ~ 1,
            start = c(Asym = 103, R0 = -8.5, lrc = -3.3))
newLoblolly <- data.frame(age = c(5,10,15,20,25,30),
                        Seed = rep(301,6))
predict(fml, newLoblolly, level = 0:1)
```

---

```
print.summary.pdMat
```

*Print a summary.pdMat Object*

---

**Description**

The standard deviations and correlations associated with the positive-definite matrix represented by `object` (considered as a variance-covariance matrix) are printed, together with the formula and the grouping level associated `object`, if any are present.

**Usage**

```
## S3 method for class 'summary.pdMat':
print(x, sigma, rdiag, Level, resid, ...)
```

**Arguments**

<code>x</code>	an object inheriting from class <code>summary.pdMat</code> , generally resulting from applying <code>summary</code> to an object inheriting from class <code>pdMat</code> .
<code>sigma</code>	an optional numeric value used as a multiplier for the square-root factor of the positive-definite matrix represented by <code>object</code> (usually the estimated within-group standard deviation from a mixed-effects model). Defaults to 1.
<code>rdig</code>	an optional integer value with the number of significant digits to be used in printing correlations. Defaults to 3.

Level	an optional character string with a description of the grouping level associated with <code>object</code> (generally corresponding to levels of grouping in a mixed-effects model). Defaults to <code>NULL</code> .
resid	an optional logical value. If <code>TRUE</code> an extra row with the "residual" standard deviation given in <code>sigma</code> will be included in the output. Defaults to <code>FALSE</code> .
...	optional arguments passed to <code>print.default</code> ; see the documentation on that method function.

print(vf1)
```

qqnorm.gls

*Normal Plot of Residuals from a gls Object***Description**

Diagnostic plots for assessing the normality of residuals the generalized least squares fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display.

**Usage**

```
## S3 method for class 'gls':
qqnorm(y, form, abline, id, idLabels, grid, ...)
```

**Arguments**

<code>y</code>	an object inheriting from class <code>gls</code> , representing a generalized least squares fitted model.
<code>form</code>	an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain <code>y</code> can be referenced. In addition, <code>y</code> itself can be referenced in the formula using the symbol <code>"."</code> . Conditional expressions on the right of a <code> </code> operator can be used to define separate panels in a Trellis display. The expression on the right hand side of <code>form</code> and to the left of a <code> </code> operator must evaluate to a residuals vector. Default is <code>~ resid(., type = "p")</code> , corresponding to a normal plot of the standardized residuals.
<code>abline</code>	an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.
<code>id</code>	an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals (random effects). Observations with absolute standardized residuals (random effects) greater than the $1 - value/2$ quantile of the standard normal distribution are identified in the plot using <code>idLabels</code> . If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.
<code>idLabels</code>	an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to <code>id</code> . If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is the innermost grouping factor.

`grid` an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if `xypplot` defaults to `TRUE`, else defaults to `FALSE`.

`...` optional arguments passed to the Trellis plot function.

**Value**

a diagnostic Trellis plot for assessing normality of residuals.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

qqnorm(fml, abline = c(0,1))
```

---

qqnorm.lme

*Normal Plot of Residuals or Random Effects from an lme Object*

---

**Description**

Diagnostic plots for assessing the normality of residuals and random effects in the linear mixed-effects fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display.

**Usage**

```
## S3 method for class 'lme':
qqnorm(y, form, abline, id, idLabels, grid, ...)
```

**Arguments**

`y` an object inheriting from class `lme`, representing a fitted linear mixed-effects model or from class `lmList`, representing a list of `lm` objects, or from class `lm`, representing a fitted linear model, or from class `nls`, representing a nonlinear least squares fitted model.

`form` an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain `y` can be referenced. In addition, `y` itself can be referenced in the formula using the symbol `"."`. Conditional expressions on the right of a `|` operator can be used to define separate panels in a Trellis display. The expression on the right hand side of `form` and to the left of a `|` operator must evaluate to a residuals vector, or a random effects matrix. Default is `~ resid(., type = "p")`, corresponding to a normal plot of the standardized residuals evaluated at the innermost level of nesting.

abline	an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.
id	an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals (random effects). Observations with absolute standardized residuals (random effects) greater than the $1 - value/2$ quantile of the standard normal distribution are identified in the plot using <code>idLabels</code> . If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.
idLabels	an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to <code>id</code> . If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is the innermost grouping factor.
grid	an optional logical value indicating whether a grid should be added to plot. Default is <code>FALSE</code> .
...	optional arguments passed to the Trellis plot function.

**Value**

a diagnostic Trellis plot for assessing normality of residuals or random effects.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates  
<bates@stat.wisc.edu>

---

Quinidine

*Quinidine Kinetics*

---

### Description

The `Quinidine` data frame has 1471 rows and 14 columns.

### Format

This data frame contains the following columns:

**Subject** a factor identifying the patient on whom the data were collected.

**time** a numeric vector giving the time (hr) at which the drug was administered or the blood sample drawn. This is measured from the time the patient entered the study.

**conc** a numeric vector giving the serum quinidine concentration (mg/L).

**dose** a numeric vector giving the dose of drug administered (mg). Although there were two different forms of quinidine administered, the doses were adjusted for differences in salt content by conversion to milligrams of quinidine base.

**interval** a numeric vector giving the when the drug has been given at regular intervals for a sufficiently long period of time to assume steady state behavior, the interval is recorded.

**Age** a numeric vector giving the age of the subject on entry to the study (yr).

**Height** a numeric vector giving the height of the subject on entry to the study (in.).

**Weight** a numeric vector giving the body weight of the subject (kg).

**Race** a factor with levels `Caucasian`, `Latin`, and `Black` identifying the race of the subject.

**Smoke** a factor with levels `no` and `yes` giving smoking status at the time of the measurement.

**Ethanol** a factor with levels `none`, `current`, `former` giving ethanol (alcohol) abuse status at the time of the measurement.

**Heart** a factor with levels `No/Mild`, `Moderate`, and `Severe` indicating congestive heart failure for the subject.

**Creatinine** an ordered factor with levels `< 50` `< = 50` indicating the creatine clearance (mg/min).

**glyco** a numeric vector giving the alpha-1 acid glycoprotein concentration (mg/dL). Often measured at the same time as the quinidine concentration.

### Details

Verme et al. (1992) analyze routine clinical data on patients receiving the drug quinidine as a treatment for cardiac arrhythmia (atrial fibrillation of ventricular arrhythmias). All patients were receiving oral quinidine doses. At irregular intervals blood samples were drawn and serum concentrations of quinidine were determined. These data are analyzed in several publications, including Davidian and Giltinan (1995, section 9.3).

---

 quinModel

---

*Model function for the Quinidine data*

---

**Description**

A model function for a model used with the `Quinidine` data. This function calls compiled C code.

**Usage**

```
quinModel(Subject, time, conc, dose, interval, lV, lKa, lCl)
```

**Arguments**

<code>Subject</code>	a factor identifying the patient on whom the data were collected.
<code>time</code>	a numeric vector giving the time (hr) at which the drug was administered or the blood sample drawn. This is measured from the time the patient entered the study.
<code>conc</code>	a numeric vector giving the serum quinidine concentration (mg/L).
<code>dose</code>	a numeric vector giving the dose of drug administered (mg). Although there were two different forms of quinidine administered, the doses were adjusted for differences in salt content by conversion to milligrams of quinidine base.
<code>interval</code>	a numeric vector giving the when the drug has been given at regular intervals for a sufficiently long period of time to assume steady state behavior, the interval is recorded.
<code>lV</code>	numeric. A vector of values of the natural log of the effective volume of distribution according to <code>Subject</code> and <code>time</code> .
<code>lKa</code>	numeric. A vector of values of the natural log of the absorption rate constant according to <code>Subject</code> and <code>time</code> .
<code>lCl</code>	numeric. A vector of values of the natural log of the clearance parameter according to <code>Subject</code> and <code>time</code> .

**Details**

See the details section of [Quinidine](#) for a description of the model function that `quinModel` evaluates.

**Value**

a numeric vector of predicted quinidine concentrations.

 Rail

*Evaluation of Stress in Railway Rails*

---

**Description**

The Rail data frame has 18 rows and 2 columns.

**Format**

This data frame contains the following columns:

**Rail** an ordered factor identifying the rail on which the measurement was made.

**travel** a numeric vector giving the travel time for ultrasonic head-waves in the rail (nanoseconds).  
The value given is the original travel time minus 36,100 nanoseconds.

**Details**

Devore (2000, Example 10.10, p. 427) cites data from an article in *Materials Evaluation* on “a study of travel time for a certain type of wave that results from longitudinal stress of rails used for railroad track.”

 random.effects

*Extract Random Effects*

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `lmList` and `lme`.

**Usage**

```
random.effects(object, ...)
ranef(object, ...)
```

**Arguments**

object any fitted model object from which random effects estimates can be extracted.  
 ... some methods for this generic function require additional arguments.

**Value**

will depend on the method function used; see the appropriate documentation.

**References**

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer, esp. pp. 100, 461.

**Examples**

```
## see the method function documentation
```

---

<code>ranef.lme</code>	<i>Extract lme Random Effects</i>
------------------------	-----------------------------------

---

**Description**

The estimated random effects at level  $i$  are represented as a data frame with rows given by the different groups at that level and columns given by the random effects. If a single level of grouping is specified, the returned object is a data frame; else, the returned object is a list of such data frames. Optionally, the returned data frame(s) may be augmented with covariates summarized over groups.

**Usage**

```
## S3 method for class 'lme':
ranef(object, augFrame, level, data, which, FUN,
       standard, omitGroupingFactor, subset, ...)
```

**Arguments**

object an object inheriting from class `lme`, representing a fitted linear mixed-effects model.

augFrame an optional logical value. If `TRUE`, the returned data frame is augmented with variables defined in `data`; else, if `FALSE`, only the coefficients are returned. Defaults to `FALSE`.

level an optional vector of positive integers giving the levels of grouping to be used in extracting the random effects from an object with multiple nested grouping levels. Defaults to all levels of grouping.

data an optional data frame with the variables to be used for augmenting the returned data frame when `augFrame = TRUE`. Defaults to the data frame used to fit `object`.

which	an optional positive integer vector specifying which columns of data should be used in the augmentation of the returned data frame. Defaults to all columns in data.
FUN	an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing data by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables in the frame such as <code>ordered</code> , <code>factor</code> , or <code>numeric</code> . The indicated function will be applied to any group-varying variables of that class. The default functions to be used are <code>mean</code> for numeric factors, and <code>Mode</code> for both <code>factor</code> and <code>ordered</code> . The <code>Mode</code> function, defined internally in <code>gsummary</code> , returns the modal or most popular value of the variable. It is different from the <code>mode</code> function that returns the S-language mode of the variable.
standard	an optional logical value indicating whether the estimated random effects should be "standardized" (i.e. divided by the estimate of the standard deviation of that group of random effects). Defaults to <code>FALSE</code> .
omitGroupingFactor	an optional logical value. When <code>TRUE</code> the grouping factor itself will be omitted from the group-wise summary of data but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to <code>FALSE</code> .
subset	an optional expression indicating for which rows the random effects should be extracted.
...	some methods for this generic require additional arguments. None are used in this method.

### Value

a data frame, or list of data frames, with the estimated random effects at the grouping level(s) specified in `level` and, optionally, other covariates summarized over groups. The returned object inherits from classes `random.effects.lme` and `data.frame`.

### Author(s)

random.effects(fml, augFrame = TRUE)

```

---

```

ranef.lmList           Extract lmList Random Effects

```

---

## Description

The difference between the individual `lm` components coefficients and their average is calculated.

## Usage

```

## S3 method for class 'lmList':
ranef(object, augFrame, data, which, FUN, standard,
       omitGroupingFactor, ...)

```

## Arguments

<code>object</code>	an object inheriting from class <code>lmList</code> , representing a list of <code>lm</code> objects with a common model.
<code>augFrame</code>	an optional logical value. If <code>TRUE</code> , the returned data frame is augmented with variables defined in <code>data</code> ; else, if <code>FALSE</code> , only the coefficients are returned. Defaults to <code>FALSE</code> .
<code>data</code>	an optional data frame with the variables to be used for augmenting the returned data frame when <code>augFrame = TRUE</code> . Defaults to the data frame used to fit <code>object</code> .
<code>which</code>	an optional positive integer vector specifying which columns of <code>data</code> should be used in the augmentation of the returned data frame. Defaults to all columns in <code>data</code> .
<code>FUN</code>	an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing <code>data</code> by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If <code>FUN</code> is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If <code>FUN</code> is a list of functions, the names in the list should designate classes of variables in the frame such as <code>ordered</code> , <code>factor</code> , or <code>numeric</code> . The indicated function will be applied to any group-varying variables of that class. The default functions to be used are <code>mean</code> for numeric factors, and <code>Mode</code> for both <code>factor</code> and <code>ordered</code> . The <code>Mode</code> function, defined internally in <code>gsummary</code> , returns the modal or most popular value of the variable. It is different from the <code>mode</code> function that returns the S-language mode of the variable.
<code>standard</code>	an optional logical value indicating whether the estimated random effects should be "standardized" (i.e. divided by the corresponding estimated standard error). Defaults to <code>FALSE</code> .
<code>omitGroupingFactor</code>	an optional logical value. When <code>TRUE</code> the grouping factor itself will be omitted from the group-wise summary of <code>data</code> but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to <code>FALSE</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with the differences between the individual `lm` coefficients in `object` and their average.

RatPupWeight	<i>The weight of rat pups</i>
--------------	-------------------------------

---

**Description**

The `RatPupWeight` data frame has 322 rows and 5 columns.

**Format**

This data frame contains the following columns:

**weight** a numeric vector

**sex** a factor with levels `Male` `Female`

**Litter** an ordered factor with levels `9 < 8 < 7 < 4 < 2 < 10 < 1 < 3 < 5 < 6 < 21 < 22 < 24 < 27 < 26 < 25 < 23 < 17 < 11 < 14 < 13 < 15 < 16 < 20 < 19 < 18 < 12`

**Lsize** a numeric vector

**Treatment** an ordered factor with levels `Control < Low < High`

`recalc`*Recalculate Condensed Linear Model Object*

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `corStruct`, `modelStruct`, `reStruct`, and `varFunc`.

**Usage**

```
recalc(object, conLin, ...)
```

**Arguments**

<code>object</code>	any object which induces a recalculation of the condensed linear model object <code>conLin</code> .
<code>conLin</code>	a condensed linear model object, consisting of a list with components " <code>Xy</code> ", corresponding to a regression matrix ( $X$ ) combined with a response vector ( $y$ ), and " <code>logLik</code> ", corresponding to the log-likelihood of the underlying model.
<code>...</code>	some methods for this generic can take additional arguments.

**Value**

the recalculated condensed linear model object.

**Note**

This function is only used inside model fitting functions, such as `lme` and `gls`, that require recalculation of a condensed linear model object.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

**Examples**

```
## see the method function documentation
```

---

recalc.corStruct     *Recalculate for corStruct Object*

---

### Description

This method function pre-multiplies the "Xy" component of `conLin` by the transpose square-root factor(s) of the correlation matrix (matrices) associated with `object` and adds the log-likelihood contribution of `object`, given by `logLik(object)`, to the "logLik" component of `conLin`.

### Usage

```
## S3 method for class 'corStruct':
recalc(object, conLin, ...)
```

### Arguments

<code>object</code>	an object inheriting from class <code>corStruct</code> , representing a correlation structure.
<code>conLin</code>	a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

### Value

the recalculated condensed linear model object.

### Note

This method function is only used inside model fitting functions, such as `lme` and `gls`, that allow correlated error terms.

### Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates  
<bates@stat.wisc.edu>

---

`recalc.modelStruct` *Recalculate for a modelStruct Object*

---

**Description**

This method function recalculates the condensed linear model object using each element of `object` sequentially from last to first.

**Usage**

```
## S3 method for class 'modelStruct':  
recalc(object, conLin, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>modelStruct</code> , representing a list of model components, such as <code>corStruct</code> and <code>varFunc</code> objects.
<code>conLin</code>	an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model. Defaults to <code>attr(object, "conLin")</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

the recalculated condensed linear model object.

**Note**

This method function is generally only used inside model fitting functions, such as `lme` and `gls`, that allow model components, such as correlated error terms and variance functions.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[recalc.corStruct](#), [recalc.reStruct](#), [recalc.varFunc](#)

---

recalc.reStruct      *Recalculate for an reStruct Object*

---

### Description

The log-likelihood, or restricted log-likelihood, of the Gaussian linear mixed-effects model represented by `object` and `conLin` (assuming spherical within-group covariance structure), evaluated at `coef(object)` is calculated and added to the `logLik` component of `conLin`. The `settings` attribute of `object` determines whether the log-likelihood, or the restricted log-likelihood, is to be calculated. The computational methods for the (restricted) log-likelihood calculations are described in Bates and Pinheiro (1998).

### Usage

```
## S3 method for class 'reStruct':
recalc(object, conLin, ...)
```

### Arguments

<code>object</code>	an object inheriting from class <code>reStruct</code> , representing a random effects structure and consisting of a list of <code>pdMat</code> objects.
<code>conLin</code>	a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

### Value

the condensed linear model with its `logLik` component updated.

### Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

### See Also

[logLik](#), [lme](#), [recalc](#), [reStruct](#)

---

recalc.varFunc      *Recalculate for varFunc Object*

---

### Description

This method function pre-multiplies the "Xy" component of `conLin` by a diagonal matrix with diagonal elements given by the weights corresponding to the variance structure represented by `object` and adds the log-likelihood contribution of `object`, given by `logLik(object)`, to the "logLik" component of `conLin`.

**Usage**

```
## S3 method for class 'varFunc':
recalc(object, conLin, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>varFunc</code> , representing a variance function structure.
<code>conLin</code>	a condensed linear model object, consisting of a list with components " <code>Xy</code> ", corresponding to a regression matrix ( <code>X</code> ) combined with a response vector ( <code>y</code> ), and " <code>logLik</code> ", corresponding to the log-likelihood of the underlying model.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

the recalculated condensed linear model object.

**Note**

This method function is only used inside model fitting functions, such as `lme` and `gls`, that allow heteroscedastic error terms.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

---

`residuals.gls`*Extract gls Residuals*

---

**Description**

The residuals for the linear model represented by `object` are extracted.

**Usage**

```
## S3 method for class 'gls':  
residuals(object, type, ...)
```

**Arguments**

object	an object inheriting from class <code>gls</code> , representing a generalized least squares fitted linear model, or from class <code>gnls</code> , representing a generalized nonlinear least squares fitted linear model.
type	an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".
...	some methods for this generic function require additional arguments. None are used in this method.

**Value**

a vector with the residuals for the linear model represented by `object`.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[gls](#)

**Examples**

```

          correlation = corAR1(form = ~ 1 | Mare))
residuals(fml)
```

---

residuals.glsStruct

*Calculate glsStruct Residuals*

---

**Description**

The residuals for the linear model represented by `object` are extracted.

**Usage**

```
## S3 method for class 'glsStruct':
residuals(object, glsFit, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>glsStruct</code> , representing a list of linear model components, such as <code>corStruct</code> and <code>varFunc</code> objects.
<code>glsFit</code>	an optional list with components <code>logLik</code> (log-likelihood), <code>beta</code> (coefficients), <code>sigma</code> (standard deviation for error term), <code>varBeta</code> (coefficients' covariance matrix), <code>fitted</code> (fitted values), and <code>residuals</code> (residuals). Defaults to <code>attr(object, "glsFit")</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with the residuals for the linear model represented by `object`.

**Note**

This method function is primarily used inside `gls` and `residuals.gls`.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

`residuals.gnlsStruct`

*Calculate gnlsStruct Residuals*

---

**Description**

The residuals for the nonlinear model represented by `object` are extracted.

**Usage**

```
## S3 method for class 'gnlsStruct':
residuals(object, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>gnlsStruct</code> , representing a list of model components, such as <code>corStruct</code> and <code>varFunc</code> objects, and attributes specifying the underlying nonlinear model and the response variable.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with the residuals for the nonlinear model represented by `object`.

**Note**

This method function is primarily used inside `gnls` and `residuals.gnls`.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

---

residuals.lme      *Extract lme Residuals*

---

**Description**

The residuals at level  $i$  are obtained by subtracting the fitted levels at that level from the response vector (and dividing by the estimated within-group standard error, if `type="pearson"`). The fitted values at level  $i$  are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to  $i$ .

**Usage**

```
## S3 method for class 'lme':
residuals(object, level, type, asList, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>lme</code> , representing a fitted linear mixed-effects model.
<code>level</code>	an optional integer vector giving the level(s) of grouping to be used in extracting the residuals from <code>object</code> . Level values increase from outermost to innermost grouping, with level zero corresponding to the population residuals. Defaults to the highest or innermost level of grouping.
<code>type</code>	an optional character string specifying the type of residuals to be used. If <code>"response"</code> , the <code>"raw"</code> residuals (observed - fitted) are used; else, if <code>"pearson"</code> , the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if <code>"normalized"</code> , the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to <code>"pearson"</code> .
<code>asList</code>	an optional logical value. If <code>TRUE</code> and a single value is given in <code>level</code> , the returned object is a list with the residuals split by groups; else the returned value is either a vector or a data frame, according to the length of <code>level</code> . Defaults to <code>FALSE</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

if a single level of grouping is specified in `level`, the returned value is either a list with the residuals split by groups (`asList = TRUE`) or a vector with the residuals (`asList = FALSE`); else, when multiple grouping levels are specified in `level`, the returned object is a data frame with columns given by the residuals at different levels and the grouping factors. For a vector or data frame result the `naresid` method is applied.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[lme](#), [fitted.lme](#)

```
fml <- lme(distance ~ age + Sex, data = Orthodont, random = ~ 1)
residuals(fml, level = 0:1)
```

---

```
residuals.lmeStruct
```

*Calculate lmeStruct Residuals*

---

**Description**

The residuals at level  $i$  are obtained by subtracting the fitted values at that level from the response vector. The fitted values at level  $i$  are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to  $i$ .

**Usage**

```
## S3 method for class 'lmeStruct':
residuals(object, level, conLin, lmeFit, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>lmeStruct</code> , representing a list of linear mixed-effects model components, such as <code>reStruct</code> , <code>corStruct</code> , and <code>varFunc</code> objects.
<code>level</code>	an optional integer vector giving the level(s) of grouping to be used in extracting the residuals from <code>object</code> . Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.
<code>conLin</code>	an optional condensed linear model object, consisting of a list with components <code>"Xy"</code> , corresponding to a regression matrix ( $X$ ) combined with a response vector ( $y$ ), and <code>"logLik"</code> , corresponding to the log-likelihood of the underlying <code>lme</code> model. Defaults to <code>attr(object, "conLin")</code> .

`lmeFit` an optional list with components `beta` and `b` containing respectively the fixed effects estimates and the random effects estimates to be used to calculate the residuals. Defaults to `attr(object, "lmeFit")`.

`...` some methods for this generic accept optional arguments.

**Value**

if a single level of grouping is specified in `level`, the returned value is a vector with the residuals at the desired level; else, when multiple grouping levels are specified in `level`, the returned object is a matrix with columns given by the residuals at different levels.

**Note**

This method function is primarily used within the `lme` function.

`residuals.lmList` *Extract lmList Residuals*

---

**Description**

The residuals are extracted from each `lm` component of `object` and arranged into a list with as many components as `object`, or combined into a single vector.

**Usage**

```
## S3 method for class 'lmList':
residuals(object, type, subset, asList, ...)
```

**Arguments**

`object` an object inheriting from class `lmList`, representing a list of `lm` objects with a common model.

`subset` an optional character or integer vector naming the `lm` components of `object` from which the residuals are to be extracted. Default is `NULL`, in which case all components are used.

`type` an optional character string specifying the type of residuals to be extracted. Options include `"response"` for the "raw" residuals (observed - fitted), `"pearson"` for the standardized residuals (raw residuals divided by the estimated residual standard error) using different standard errors for each `lm` fit, and `"pooled.pearson"` for the standardized residuals using a pooled estimate of the residual standard error. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to `"response"`.

`asList` an optional logical value. If `TRUE`, the returned object is a list with the residuals split by groups; else the returned value is a vector. Defaults to `FALSE`.

`...` some methods for this generic require additional arguments. None are used in this method.

### Value

a list with components given by the residuals of each `lm` component of `object`, or a vector with the residuals for all `lm` components of `object`.

### Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

### See Also

### Examples

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
residuals(fm1)
```

---

residuals.nlmeStruct

*Calculate nlmeStruct Residuals*

---

### Description

The residuals at level  $i$  are obtained by subtracting the fitted values at that level from the response vector. The fitted values at level  $i$  are obtained by adding together the contributions from the estimated fixed effects and the estimated random effects at levels less or equal to  $i$  and evaluating the model function at the resulting estimated parameters.

### Usage

```
## S3 method for class 'nlmeStruct':
residuals(object, level, conLin, ...)
```

### Arguments

`object` an object inheriting from class `nlmeStruct`, representing a list of mixed-effects model components, such as `reStruct`, `corStruct`, and `varFunc` objects.

`level` an optional integer vector giving the level(s) of grouping to be used in extracting the residuals from `object`. Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.

conLin an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying nlme model. Defaults to `attr(object, "conLin")`.

... optional arguments to the residuals generic. Not used.

### Value

if a single level of grouping is specified in `level`, the returned value is a vector with the residuals at the desired level; else, when multiple grouping levels are specified in `level`, the returned object is a matrix with columns given by the residuals at different levels.

### Note

This method function is primarily used within the `nlme` function.

### Author(s)

reStruct

*Random Effects Structure*

---

### Description

This function is a constructor for the `reStruct` class, representing a random effects structure and consisting of a list of `pdMat` objects, plus a `settings` attribute containing information for the optimization algorithm used to fit the associated mixed-effects model.

### Usage

```
reStruct(object, pdClass, REML, data)
## S3 method for class 'reStruct':
print(x, sigma, reEstimates, verbose, ...)
```

**Arguments**

<code>object</code>	any of the following: (i) a one-sided formula of the form $\sim x_1 + \dots + x_n \mid g_1 / \dots / g_m$ , with $x_1 + \dots + x_n$ specifying the model for the random effects and $g_1 / \dots / g_m$ the grouping structure ( $m$ may be equal to 1, in which case no $/$ is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a list of one-sided formulas of the form $\sim x_1 + \dots + x_n \mid g$ , with possibly different random effects models for each grouping level. The order of nesting will be assumed the same as the order of the elements in the list; (iii) a one-sided formula of the form $\sim x_1 + \dots + x_n$ , or a <code>pdMat</code> object with a formula (i.e. a non-NULL value for <code>formula(object)</code> ), or a list of such formulas or <code>pdMat</code> objects. In this case, the grouping structure formula will be derived from the data used to fit the mixed-effects model, which should inherit from class <code>groupedData</code> ; (iv) a named list of formulas or <code>pdMat</code> objects as in (iii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the elements in the list; (v) an <code>reStruct</code> object.
<code>pdClass</code>	an optional character string with the name of the <code>pdMat</code> class to be used for the formulas in <code>object</code> . Defaults to <code>"pdSymm"</code> which corresponds to a general positive-definite matrix.
<code>REML</code>	an optional logical value. If <code>TRUE</code> , the associated mixed-effects model will be fitted using restricted maximum likelihood; else, if <code>FALSE</code> , maximum likelihood will be used. Defaults to <code>FALSE</code> .
<code>data</code>	an optional data frame in which to evaluate the variables used in the random effects formulas in <code>object</code> . It is used to obtain the levels for <code>factors</code> , which affect the dimensions and the row/column names of the underlying <code>pdMat</code> objects. If <code>NULL</code> , no attempt is made to obtain information on <code>factors</code> appearing in the formulas. Defaults to the parent frame from which the function was called.
<code>x</code>	an object inheriting from class <code>reStruct</code> to be printed.
<code>sigma</code>	an optional numeric value used as a multiplier for the square-root factors of the <code>pdMat</code> components (usually the estimated within-group standard deviation from a mixed-effects model). Defaults to 1.
<code>reEstimates</code>	an optional list with the random effects estimates for each level of grouping. Only used when <code>verbose = TRUE</code> .
<code>verbose</code>	an optional logical value determining if the random effects estimates should be printed. Defaults to <code>FALSE</code> .
<code>...</code>	Optional arguments can be given to other methods for this generic. None are used in this method.

**Value**

an object inheriting from class `reStruct`, representing a random effects structure.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

groupedData, lme, pdMat, solve.reStruct, summary.reStruct, update.reStruct

**Examples**

```
rs1 <- reStruct(list(Dog = ~day, Side = ~1), data = Pixel)
rs1
```

---

simulate.lme

*Simulate results from lme models*

---

**Description**

The model object is fit to the data. Using the fitted values of the parameters, `nsim` new data vectors from this model are simulated. Both `m1` and `m2` are fit by maximum likelihood (ML) and/or by restricted maximum likelihood (REML) to each of the simulated data vectors.

**Usage**

```
simulate.lme(object, nsim, seed, m2, method, niterEM, useGen, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>lme</code> , representing a fitted linear mixed-effects model, or a list containing an <code>lme</code> model specification. If given as a list, it should contain components <code>fixed</code> , <code>data</code> , and <code>random</code> with values suitable for a call to <code>lme</code> . This argument defines the null model.
<code>m2</code>	an <code>lme</code> object, or a list, like <code>m1</code> containing a second <code>lme</code> model specification. This argument defines the alternative model. If given as a list, only those parts of the specification that change between model <code>m1</code> and <code>m2</code> need to be specified.
<code>seed</code>	an optional integer that is passed to <code>set.seed</code> . Defaults to a random integer.
<code>method</code>	an optional character array. If it includes "REML" the models are fit by maximizing the restricted log-likelihood. If it includes "ML" the log-likelihood is maximized. Defaults to <code>c("REML", "ML")</code> , in which case both methods are used.
<code>nsim</code>	an optional positive integer specifying the number of simulations to perform. Defaults to <b>1</b> . <b>This has changed. Previously the default was 1000.</b>
<code>niterEM</code>	an optional integer vector of length 2 giving the number of iterations of the EM algorithm to apply when fitting the <code>m1</code> and <code>m2</code> to each simulated set of data. Defaults to <code>c(40, 200)</code> .
<code>useGen</code>	an optional logical value. If <code>TRUE</code> , numerical derivatives are used to obtain the gradient and the Hessian of the log-likelihood in the optimization algorithm in the <code>ms</code> function. If <code>FALSE</code> , the default algorithm in <code>ms</code> for functions that do not incorporate gradient and Hessian attributes is used. Default depends on the <code>pdMat</code> classes used in <code>m1</code> and <code>m2</code> : if both are standard classes (see <a href="#">pdClasses</a> ) then defaults to <code>TRUE</code> , otherwise defaults to <code>FALSE</code> .
<code>...</code>	optional additional arguments. None are used.

**Value**

an object of class `simulate.lme` with components `null` and `alt`. Each of these has components `ML` and/or `REML` which are matrices. An attribute called `Random.seed` contains the seed that was used for the random number generator.

                  random = ~ 1 | Subject), nsim = 1000,
              m2 = list(random = ~ age | Subject))

## End(Not run)
```

---

solve.pdMat

*Calculate Inverse of a Positive-Definite Matrix*

---

**Description**

The positive-definite matrix represented by `a` is inverted and assigned to `a`.

**Usage**

```
## S3 method for class 'pdMat':
solve(a, b, ...)
```

**Arguments**

`a` an object inheriting from class `pdMat`, representing a positive definite matrix.

`b` this argument is only included for consistency with the generic function and is not used in this method function.

`...` some methods for this generic require additional arguments. None are used in this method.

**Value**

a `pdMat` object similar to `a`, but with coefficients corresponding to the inverse of the positive-definite matrix represented by `a`.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates  
<bates@stat.wisc.edu>

**See Also**

```

---

solve.reStruct      *Apply Solve to an reStruct Object*

---

**Description**

Solve is applied to each `pdMat` component of `a`, which results in inverting the positive-definite matrices they represent.

**Usage**

```
## S3 method for class 'reStruct':
solve(a, b, ...)
```

**Arguments**

<code>a</code>	an object inheriting from class <code>reStruct</code> , representing a random effects structure and consisting of a list of <code>pdMat</code> objects.
<code>b</code>	this argument is only included for consistency with the generic function and is not used in this method function.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

an `reStruct` object similar to `a`, but with the `pdMat` components representing the inverses of the matrices represented by the components of `a`.

Soybean

*Growth of soybean plants***Description**

The Soybean data frame has 412 rows and 5 columns.

**Format**

This data frame contains the following columns:

**Plot** a factor giving a unique identifier for each plot.

**Variety** a factor indicating the variety; Forrest (F) or Plant Introduction \#416937 (P).

**Year** a factor indicating the year the plot was planted.

**Time** a numeric vector giving the time the sample was taken (days after planting).

**weight** a numeric vector giving the average leaf weight per plant (g).

**Details**

These data are described in Davidian and Giltinan (1995, 1.1.3, p.7) as “Data from an experiment to compare growth patterns of two genotypes of soybeans: Plant Introduction \#416937 (P), an experimental strain, and Forrest (F), a commercial variety.”

**Examples**

```
summary(fm1 <- nlsList(SSlogis, data = Soybean))
```

---

splitFormula                      *Split a Formula*

---

### Description

Splits the right hand side of `form` into a list of subformulas according to the presence of `sep`. The left hand side of `form`, if present, will be ignored. The length of the returned list will be equal to the number of occurrences of `sep` in `form` plus one.

### Usage

```
splitFormula(form, sep)
```

### Arguments

`form`                      a formula object.  
`sep`                        an optional character string specifying the separator to be used for splitting the formula. Defaults to `" / "`.

### Value

a list of formulas, corresponding to the split of `form` according to `sep`.

### Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates  
<bates@stat.wisc.edu>

```

---

Spruce                              *Growth of Spruce Trees*

---

### Description

The `Spruce` data frame has 1027 rows and 4 columns.

### Format

This data frame contains the following columns:

**Tree** a factor giving a unique identifier for each tree.

**days** a numeric vector giving the number of days since the beginning of the experiment.

**logSize** a numeric vector giving the logarithm of an estimate of the volume of the tree trunk.

**plot** a factor identifying the plot in which the tree was grown.

**Details**

Diggle, Liang, and Zeger (1994, Example 1.3, page 5) describe data on the growth of spruce trees that have been exposed to an ozone-rich atmosphere or to a normal atmosphere.

---

summary.corStruct *Summarize a corStruct Object*

---

**Description**

This method function prepares `object` to be printed using the `print.summary` method, by changing its class and adding a `structName` attribute to it.

**Usage**

```
## S3 method for class 'corStruct':
summary(object, structName, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>corStruct</code> , representing a correlation structure.
<code>structName</code>	an optional character string defining the type of correlation structure associated with <code>object</code> , to be used in the <code>print.summary</code> method. Defaults to <code>class(object)[1]</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

an object identical to `object`, but with its class changed to `summary.corStruct` and an additional attribute `structName`. The returned value inherits from the same classes as `object`.

**Author(s)**

Jose Pinheiro and Douglas Bates

**See Also**

```

---

`summary.gls`*Summarize a gls Object*

---

**Description**

Additional information about the linear model fit represented by `object` is extracted and included as components of `object`.

**Usage**

```
## S3 method for class 'gls':  
summary(object, verbose, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>gls</code> , representing a generalized least squares fitted linear model.
<code>verbose</code>	an optional logical value used to control the amount of output when the object is printed. Defaults to <code>FALSE</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

an object inheriting from class `summary.gls` with all components included in `object` (see [glsObject](#) for a full description of the components) plus the following components:

<code>corBeta</code>	approximate correlation matrix for the coefficients estimates
<code>tTable</code>	a data frame with columns <code>Value</code> , <code>Std. Error</code> , <code>t-value</code> , and <code>p-value</code> representing respectively the coefficients estimates, their approximate standard errors, the ratios between the estimates and their standard errors, and the associated p-value under a <i>t</i> approximation. Rows correspond to the different coefficients.
<code>residuals</code>	if more than five observations are used in the <code>gls</code> fit, a vector with the minimum, first quartile, median, third quartile, and maximum of the residuals distribution; else the residuals.
<code>AIC</code>	the Akaike Information Criterion corresponding to <code>object</code> .
<code>BIC</code>	the Bayesian Information Criterion corresponding to <code>object</code> .

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

```
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
           correlation = corAR1(form = ~ 1 | Mare))
summary(fm1)
```

summary.lme

*Summarize an lme Object***Description**

Additional information about the linear mixed-effects fit represented by `object` is extracted and included as components of `object`. The returned object is suitable for printing with the `print.summary.lme` method.

**Usage**

```
## S3 method for class 'lme':
summary(object, adjustSigma, verbose, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>lme</code> , representing a fitted linear mixed-effects model.
<code>adjustSigma</code>	an optional logical value. If <code>TRUE</code> and the estimation method used to obtain <code>object</code> was maximum likelihood, the residual standard error is multiplied by $\sqrt{n_{obs}/(n_{obs} - n_{par})}$ , converting it to a REML-like estimate. This argument is only used when a single fitted object is passed to the function. Default is <code>TRUE</code> .
<code>verbose</code>	an optional logical value used to control the amount of output in the <code>print.summary.lme</code> method. Defaults to <code>FALSE</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

an object inheriting from class `summary.lme` with all components included in `object` (see [lmeObject](#) for a full description of the components) plus the following components:

<code>corFixed</code>	approximate correlation matrix for the fixed effects estimates
<code>tTable</code>	a data frame with columns <code>Value</code> , <code>Std. Error</code> , <code>DF</code> , <code>t-value</code> , and <code>p-value</code> representing respectively the fixed effects estimates, their approximate standard errors, the denominator degrees of freedom, the ratios between the estimates and their standard errors, and the associated p-value from a t distribution. Rows correspond to the different fixed effects.
<code>residuals</code>	if more than five observations are used in the <code>lme</code> fit, a vector with the minimum, first quartile, median, third quartile, and maximum of the innermost grouping level residuals distribution; else the innermost grouping level residuals.
<code>AIC</code>	the Akaike Information Criterion corresponding to <code>object</code> .
<code>BIC</code>	the Bayesian Information Criterion corresponding to <code>object</code> .

---

summary.lmList      *Summarize an lmList Object*

---

**Description**

The `summary.lm` method is applied to each `lm` component of `object` to produce summary information on the individual fits, which is organized into a list of summary statistics. The returned object is suitable for printing with the `print.summary.lmList` method.

**Usage**

```
## S3 method for class 'lmList':
summary(object, pool, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>lmList</code> , representing a list of <code>lm</code> fitted objects.
<code>pool</code>	an optional logical value indicating whether a pooled estimate of the residual standard error should be used. Default is <code>attr(object, "pool")</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a list with summary statistics obtained by applying `summary.lm` to the elements of `object`, inheriting from class `summary.lmList`. The components of `value` are:

<code>call</code>	a list containing an image of the <code>lmList</code> call that produced <code>object</code> .
<code>coefficients</code>	a three dimensional array with summary information on the <code>lm</code> coefficients. The first dimension corresponds to the names of the <code>object</code> components, the second dimension is given by "Value", "Std. Error", "t value", and "Pr(> t )", corresponding, respectively, to the coefficient estimates and their associated standard errors, t-values, and p-values. The third dimension is given by the coefficients names.
<code>correlation</code>	a three dimensional array with the correlations between the individual <code>lm</code> coefficient estimates. The first dimension corresponds to the names of the <code>object</code> components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the correlations between that coefficient and the remaining coefficients, by <code>lm</code> component.

<code>cov.unscaled</code>	a three dimensional array with the unscaled variances/covariances for the individual <code>lm</code> coefficient estimates (giving the estimated variance/covariance for the coefficients, when multiplied by the estimated residual errors). The first dimension corresponds to the names of the <code>object</code> components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the unscaled covariances between that coefficient and the remaining coefficients, by <code>lm</code> component.
<code>df</code>	an array with the number of degrees of freedom for the model and for residuals, for each <code>lm</code> component.
<code>df.residual</code>	the total number of degrees of freedom for residuals, corresponding to the sum of residuals <code>df</code> of all <code>lm</code> components.
<code>fstatistics</code>	an array with the F test statistics and corresponding degrees of freedom, for each <code>lm</code> component.
<code>pool</code>	the value of the <code>pool</code> argument to the function.
<code>r.squared</code>	a vector with the multiple R-squared statistics for each <code>lm</code> component.
<code>residuals</code>	a list with components given by the residuals from individual <code>lm</code> fits.
<code>RSE</code>	the pooled estimate of the residual standard error.
<code>sigma</code>	a vector with the residual standard error estimates for the individual <code>lm</code> fits.
<code>terms</code>	the terms object used in fitting the individual <code>lm</code> components.

summary.modelStruct

*Summarize a modelStruct Object*

---

**Description**

This method function applies `summary` to each element of `object`.

**Usage**

```
## S3 method for class 'modelStruct':
summary(object, ...)
```

**Arguments**

- `object` an object inheriting from class `modelStruct`, representing a list of model components, such as `reStruct`, `corStruct` and `varFunc` objects.
- `...` some methods for this generic require additional arguments. None are used in this method.

**Value**

a list with elements given by the summarized components of `object`. The returned value is of class `summary.modelStruct`, also inheriting from the same classes as `object`.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[reStruct](#), [summary](#)

**Examples**

```

---

summary.nlsList      *Summarize an nlsList Object*

---

**Description**

The `summary` function is applied to each `nls` component of `object` to produce summary information on the individual fits, which is organized into a list of summary statistics. The returned object is suitable for printing with the `print.summary.nlsList` method.

**Usage**

```
## S3 method for class 'nlsList':
summary(object, ...)
```

**Arguments**

- `object` an object inheriting from class `nlsList`, representing a list of `nls` fitted objects.
- `...` optional arguments to the `summary.lmList` method. One such optional argument is `pool`, a logical value indicating whether a pooled estimate of the residual standard error should be used. Default is `attr(object, "pool")`.

**Value**

a list with summary statistics obtained by applying `summary` to the elements of `object`, inheriting from class `summary.nlsList`. The components of `value` are:

<code>call</code>	a list containing an image of the <code>nlsList</code> call that produced <code>object</code> .
<code>parameters</code>	a three dimensional array with summary information on the <code>nls</code> coefficients. The first dimension corresponds to the names of the <code>object</code> components, the second dimension is given by "Value", "Std. Error", "t value", and "Pr(> t )", corresponding, respectively, to the coefficient estimates and their associated standard errors, t-values, and p-values. The third dimension is given by the coefficients names.
<code>correlation</code>	a three dimensional array with the correlations between the individual <code>nls</code> coefficient estimates. The first dimension corresponds to the names of the <code>object</code> components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the correlations between that coefficient and the remaining coefficients, by <code>nls</code> component.
<code>cov.unscaled</code>	a three dimensional array with the unscaled variances/covariances for the individual <code>lm</code> coefficient estimates (giving the estimated variance/covariance for the coefficients, when multiplied by the estimated residual errors). The first dimension corresponds to the names of the <code>object</code> components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the unscaled covariances between that coefficient and the remaining coefficients, by <code>nls</code> component.
<code>df</code>	an array with the number of degrees of freedom for the model and for residuals, for each <code>nls</code> component.
<code>df.residual</code>	the total number of degrees of freedom for residuals, corresponding to the sum of residuals <code>df</code> of all <code>nls</code> components.
<code>pool</code>	the value of the <code>pool</code> argument to the function.
<code>RSE</code>	the pooled estimate of the residual standard error.
<code>sigma</code>	a vector with the residual standard error estimates for the individual <code>lm</code> fits.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

---

`summary.pdMat`*Summarize a pdMat Object*

---

## Description

Attributes `structName` and `noCorrelation`, with the values of the corresponding arguments to the method function, are appended to `object` and its class is changed to `summary.pdMat`.

## Usage

```
## S3 method for class 'pdMat':
summary(object, structName, noCorrelation, ...)
```

## Arguments

<code>object</code>	an object inheriting from class <code>pdMat</code> , representing a positive definite matrix.
<code>structName</code>	an optional character string with a description of the <code>pdMat</code> class. Default depends on the method function: "Blocked" for <code>pdBlocked</code> , "Compound Symmetry" for <code>pdCompSymm</code> , "Diagonal" for <code>pdDiag</code> , "Multiple of an Identity" for <code>pdIdent</code> , "General Positive-Definite, Natural Parametrization" for <code>pdNatural</code> , "General Positive-Definite" for <code>pdSymm</code> , and <code>data.class(object)</code> for <code>pdMat</code> .
<code>noCorrelation</code>	an optional logical value indicating whether correlations are to be printed in <code>print.summary.pdMat</code> . Default depends on the method function: FALSE for <code>pdDiag</code> and <code>pdIdent</code> , and TRUE for all other classes.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

## Value

an object similar to `object`, with additional attributes `structName` and `noCorrelation`, inheriting from class `summary.pdMat`.

## Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

## See Also

## Examples

```
summary(pdSymm(diag(4)))
```

---

summary.varFunc      *Summarize varFunc Object*

---

### Description

A `structName` attribute, with the value of corresponding argument, is appended to `object` and its class is changed to `summary.varFunc`.

### Usage

```
## S3 method for class 'varFunc':  
summary(object, structName, ...)
```

### Arguments

<code>object</code>	an object inheriting from class <code>varFunc</code> , representing a variance function structure.
<code>structName</code>	an optional character string with a description of the <code>varFunc</code> class. Default depends on the method function: "Combination of variance functions" for <code>varComb</code> , "Constant plus power of covariate" for <code>varConstPower</code> , "Exponential of variance covariate" for <code>varExp</code> , "Different standard deviations per stratum" for <code>varIdent</code> , "Power of variance covariate" for <code>varPower</code> , and <code>data.class(object)</code> for <code>varFunc</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

### Value

an object similar to `object`, with an additional attribute `structName`, inheriting from class `summary.varFunc`.

### Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

### See Also

```

---

Tetracycline1

*Pharmacokinetics of tetracycline*

---

### Description

The Tetracycline1 data frame has 40 rows and 4 columns.

### Format

This data frame contains the following columns:

**conc** a numeric vector

**Time** a numeric vector

**Subject** an ordered factor with levels 5 < 3 < 2 < 4 < 1

**Formulation** a factor with levels tetrachel tetracyn

### Source

Pinheiro, J. C. and Bates, D. M. (2000), *Mixed-Effects Models in S and S-PLUS*, Springer, New York.

---

Tetracycline2

*Pharmacokinetics of tetracycline*

---

### Description

The Tetracycline2 data frame has 40 rows and 4 columns.

### Format

This data frame contains the following columns:

**conc** a numeric vector

**Time** a numeric vector

**Subject** an ordered factor with levels 4 < 5 < 2 < 1 < 3

**Formulation** a factor with levels Berkmycin tetramycin

### Source

Pinheiro, J. C. and Bates, D. M. (2000), *Mixed-Effects Models in S and S-PLUS*, Springer, New York.

---

update.modelStruct *Update a modelStruct Object*

---

### Description

This method function updates each element of `object`, allowing the access to `data`.

### Usage

```
## S3 method for class 'modelStruct':
update(object, data, ...)
```

### Arguments

<code>object</code>	an object inheriting from class <code>modelStruct</code> , representing a list of model components, such as <code>corStruct</code> and <code>varFunc</code> objects.
<code>data</code>	a data frame in which to evaluate the variables needed for updating the elements of <code>object</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

### Value

an object similar to `object` (same class, length, and names), but with updated elements.

### Note

This method function is primarily used within model fitting functions, such as `lme` and `gls`, that allow model components such as variance functions.

### Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

### See Also

[reStruct](#)

---

update.varFunc *Update varFunc Object*

---

### Description

If the `formula(object)` includes a `"."` term, representing a fitted object, the variance covariate needs to be updated upon completion of an optimization cycle (in which the variance function weights are kept fixed). This method function allows a reevaluation of the variance covariate using the current fitted object and, optionally, other variables in the original data.

**Usage**

```
## S3 method for class 'varFunc':
update(object, data, ...)
```

**Arguments**

`object` an object inheriting from class `varFunc`, representing a variance function structure.

`data` a list with a component named "." with the current version of the fitted object (from which fitted values, coefficients, and residuals can be extracted) and, if necessary, other variables used to evaluate the variance covariate(s).

... some methods for this generic require additional arguments. None are used in this method.

**Value**

if `formula(object)` includes a "." term, an `varFunc` object similar to `object`, but with the variance covariate reevaluated at the current fitted object value; else `object` is returned unchanged.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[needUpdate](#), [covariate<-varFunc](#)

---

varClasses	<i>Variance Function Classes</i>
------------	----------------------------------

---

**Description**

Standard classes of variance function structures (`varFunc`) available in the `nlme` library. Covariates included in the variance function, denoted by variance covariates, may involve functions of the fitted model object, such as the fitted values and the residuals. Different coefficients may be assigned to the levels of a classification factor.

**Value**

Available standard classes ():

<code>varExp</code>	exponential of a variance covariate.
<code>varPower</code>	power of a variance covariate.
<code>varConstPower</code>	constant plus power of a variance covariate.
<code>varIdent</code>	constant variance(s), generally used to allow different variances according to the levels of a classification factor.
<code>varFixed</code>	fixed weights, determined by a variance covariate.
<code>varComb</code>	combination of variance functions.

**Note**

Users may define their own `varFunc` classes by specifying a constructor function and, at a minimum, methods for the functions `coef`, `coef<-`, and `initialize`. For examples of these functions, see the methods for class `varPower`.

---

varComb

*Combination of Variance Functions*

---

**Description**

This function is a constructor for the `varComb` class, representing a combination of variance functions. The corresponding variance function is equal to the product of the variance functions of the `varFunc` objects listed in . . . .

**Usage**

```
varComb(...)
```

**Arguments**

. . . objects inheriting from class `varFunc` representing variance function structures.

**Value**

a `varComb` object representing a combination of variance functions, also inheriting from class `varFunc`.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**References**

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

**Examples**

```
vfl <- varComb(varIdent(form = ~1|Sex), varPower())
```

---

varConstPower                      *Constant Plus Power Variance Function*

---

**Description**

This function is a constructor for the `varConstPower` class, representing a constant plus power variance function structure. Letting  $v$  denote the variance covariate and  $\sigma^2(v)$  denote the variance function evaluated at  $v$ , the constant plus power variance function is defined as  $\sigma^2(v) = (\theta_1 + |v|_2^{\theta_2})^2$ , where  $\theta_1, \theta_2$  are the variance function coefficients. When a grouping factor is present, different  $\theta_1, \theta_2$  are used for each factor level.

**Usage**

```
varConstPower(const, power, form, fixed)
```

**Arguments**

- `const`, `power` optional numeric vectors, or lists of numeric values, with, respectively, the coefficients for the constant and the power terms. Both arguments must have length one, unless a grouping factor is specified in `form`. If either argument has length greater than one, it must have names which identify its elements to the levels of the grouping factor defined in `form`. If a grouping factor is present in `form` and the argument has length one, its value will be assigned to all grouping levels. Only positive values are allowed for `const`. Default is `numeric(0)`, which results in a vector of zeros of appropriate length being assigned to the coefficients when `object` is initialized (corresponding to constant variance equal to one).
- `form` an optional one-sided formula of the form `~ v`, or `~ v | g`, specifying a variance covariate `v` and, optionally, a grouping factor `g` for the coefficients. The variance covariate must evaluate to a numeric vector and may involve expressions using `"."`, representing a fitted model object from which fitted values (`fitted(.)`) and residuals (`resid(.)`) can be extracted (this allows the variance covariate to be updated during the optimization of an object function). When a grouping factor is present in `form`, a different coefficient value is used for each of its levels. Several grouping variables may be simultaneously specified, separated by the `*` operator, as in `~ v | g1 * g2 * g3`. In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to `~ fitted(.)` representing a variance covariate given by the fitted values of a fitted model object and no grouping factor.
- `fixed` an optional list with components `const` and/or `power`, consisting of numeric vectors, or lists of numeric values, specifying the values at which some or all

of the coefficients in the variance function should be fixed. If a grouping factor is specified in `form`, the components of `fixed` must have names identifying which coefficients are to be fixed. Coefficients included in `fixed` are not allowed to vary during the optimization of an objective function. Defaults to `NULL`, corresponding to no fixed coefficients.

### Value

a `varConstPower` object representing a constant plus power variance function structure, also inheriting from class `varFunc`.

### Author(s)

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

### References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

### Examples

```
vf1 <- varConstPower(1.2, 0.2, form = ~age|Sex)
```

---

VarCorr

*Extract variance and correlation components*

---

### Description

This function calculates the estimated variances, standard deviations, and correlations between the random-effects terms in a linear mixed-effects model, of class `lme`, or a nonlinear mixed-effects model, of class `nlme`. The within-group error variance and standard deviation are also calculated.

### Usage

```
VarCorr(x, sigma, rdig)
```

### Arguments

<code>x</code>	a fitted model object, usually an object inheriting from class <code>lme</code> .
<code>sigma</code>	an optional numeric value used as a multiplier for the standard deviations. Default is 1.
<code>rdig</code>	an optional integer value specifying the number of digits used to represent correlation estimates. Default is 3.

**Value**

a matrix with the estimated variances, standard deviations, and correlations for the random effects. The first two columns, named `Variance` and `StdDev`, give, respectively, the variance and the standard deviations. If there are correlation components in the random effects model, the third column, named `Corr`, and the remaining unnamed columns give the estimated correlations among random effects within the same level of grouping. The within-group error variance and standard deviation are included as the last row in the matrix.

---

varExp

*Exponential Variance Function*

---

**Description**

This function is a constructor for the `varExp` class, representing an exponential variance function structure. Letting  $v$  denote the variance covariate and  $\sigma^2(v)$  denote the variance function evaluated at  $v$ , the exponential variance function is defined as  $\sigma^2(v) = \exp(2\theta v)$ , where  $\theta$  is the variance function coefficient. When a grouping factor is present, a different  $\theta$  is used for each factor level.

**Usage**

```
varExp(value, form, fixed)
```

**Arguments**

`value` an optional numeric vector, or list of numeric values, with the variance function coefficients. `Value` must have length one, unless a grouping factor is specified in `form`. If `value` has length greater than one, it must have names which identify its elements to the levels of the grouping factor defined in `form`. If a grouping factor is present in `form` and `value` has length one, its value will be assigned to all grouping levels. Default is `numeric(0)`, which results in a vector of zeros of appropriate length being assigned to the coefficients when `object` is initialized (corresponding to constant variance equal to one).

form	an optional one-sided formula of the form $\sim v$ , or $\sim v \mid g$ , specifying a variance covariate $v$ and, optionally, a grouping factor $g$ for the coefficients. The variance covariate must evaluate to a numeric vector and may involve expressions using <code>"."</code> , representing a fitted model object from which fitted values ( <code>fitted(.)</code> ) and residuals ( <code>resid(.)</code> ) can be extracted (this allows the variance covariate to be updated during the optimization of an object function). When a grouping factor is present in <code>form</code> , a different coefficient value is used for each of its levels. Several grouping variables may be simultaneously specified, separated by the <code>*</code> operator, like in $\sim v \mid g1 * g2 * g3$ . In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to $\sim fitted(.)$ representing a variance covariate given by the fitted values of a fitted model object and no grouping factor.
fixed	an optional numeric vector, or list of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. If a grouping factor is specified in <code>form</code> , <code>fixed</code> must have names identifying which coefficients are to be fixed. Coefficients included in <code>fixed</code> are not allowed to vary during the optimization of an objective function. Defaults to <code>NULL</code> , corresponding to no fixed coefficients.

**Value**

a `varExp` object representing an exponential variance function structure, also inheriting from class `varFunc`.

**Examples**

```
vf1 <- varExp(0.2, form = ~age|Sex)
```

---

varFixed

*Fixed Variance Function*

---

**Description**

This function is a constructor for the `varFixed` class, representing a variance function with fixed variances. Letting  $v$  denote the variance covariate defined in `value`, the variance function  $\sigma^2(v)$  for this class is  $\sigma^2(v) = |v|$ . The variance covariate  $v$  is evaluated once at initialization and remains fixed thereafter. No coefficients are required to represent this variance function.

**Usage**

```
varFixed(value)
```

**Arguments**

value a one-sided formula of the form  $\sim v$  specifying a variance covariate  $v$ . Grouping factors are ignored.

**Value**

a `varFixed` object representing a fixed variance function structure, also inheriting from class `varFunc`.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

---

varFunc

*Variance Function Structure*

---

**Description**

If `object` is a one-sided formula, it is used as the argument to `varFixed` and the resulting object is returned. Else, if `object` inherits from class `varFunc`, it is returned unchanged.

**Usage**

```
varFunc(object)
```

**Arguments**

object either an one-sided formula specifying a variance covariate, or an object inheriting from class `varFunc`, representing a variance function structure.

**Value**

an object from class `varFunc`, representing a variance function structure.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**Examples**

```
vf1 <- varFunc(~age)
```

---

varIdent

*Constant Variance Function*

---

**Description**

This function is a constructor for the `varIdent` class, representing a constant variance function structure. If no grouping factor is present in `form`, the variance function is constant and equal to one, and no coefficients required to represent it. When `form` includes a grouping factor with  $M > 1$  levels, the variance function allows  $M$  different variances, one for each level of the factor. For identifiability reasons, the coefficients of the variance function represent the ratios between the variances and a reference variance (corresponding to a reference group level). Therefore, only  $M - 1$  coefficients are needed to represent the variance function. By default, if the elements in `value` are unnamed, the first group level is taken as the reference level.

**Usage**

```
varIdent(value, form, fixed)
```

**Arguments**

<code>value</code>	an optional numeric vector, or list of numeric values, with the variance function coefficients. If no grouping factor is present in <code>form</code> , this argument is ignored, as the resulting variance function contains no coefficients. If <code>value</code> has length one, its value is repeated for all coefficients in the variance function. If <code>value</code> has length greater than one, it must have length equal to the number of grouping levels minus one and names which identify its elements to the levels of the grouping factor. Only positive values are allowed for this argument. Default is <code>numeric(0)</code> , which results in a vector of zeros of appropriate length being assigned to the coefficients when <code>object</code> is initialized (corresponding to constant variance equal to one).
<code>form</code>	an optional one-sided formula of the form <code>~ v</code> , or <code>~ v   g</code> , specifying a variance covariate <code>v</code> and, optionally, a grouping factor <code>g</code> for the coefficients. The variance covariate is ignored in this variance function. When a grouping factor is present in <code>form</code> , a different coefficient value is used for each of its levels less one reference level (see description section below). Several grouping variables may be simultaneously specified, separated by the <code>*</code> operator, like in <code>~ v   g1 * g2 * g3</code> . In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to <code>~ 1</code> .

`fixed` an optional numeric vector, or list of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. It must have names identifying which coefficients are to be fixed. Coefficients included in `fixed` are not allowed to vary during the optimization of an objective function. Defaults to `NULL`, corresponding to no fixed coefficients.

### Value

a `varIdent` object representing a constant variance function structure, also inheriting from class `varFunc`.

Variogram

*Calculate Semi-variogram*

---

### Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `default`, `gls` and `lme`. See the appropriate method documentation for a description of the arguments.

### Usage

```
Variogram(object, distance, ...)
```

### Arguments

`object` a numeric vector with the values to be used for calculating the semi-variogram, usually a residual vector from a fitted model.

`distance` a numeric vector with the pairwise distances corresponding to the elements of `object`. The order of the elements in `distance` must correspond to the pairs  $(1, 2)$ ,  $(1, 3)$ ,  $\dots$ ,  $(n-1, n)$ , with  $n$  representing the length of `object`, and must have length  $n(n-1)/2$ .

`...` some methods for this generic function require additional arguments.

**Value**

will depend on the method function used; see the appropriate documentation.

`Variogram.corExp` *Calculate Semi-variogram for a corExp Object*

---

**Description**

This method function calculates the semi-variogram values corresponding to the Exponential correlation model, using the estimated coefficients corresponding to `object`, at the distances defined by `distance`.

**Usage**

```
## S3 method for class 'corExp':
Variogram(object, distance, sig2, length.out, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>corExp</code> , representing an exponential spatial correlation structure.
<code>distance</code>	an optional numeric vector with the distances at which the semi-variogram is to be calculated. Defaults to <code>NULL</code> , in which case a sequence of length <code>length.out</code> between the minimum and maximum values of <code>getCovariate(object)</code> is used.
<code>sig2</code>	an optional numeric value representing the process variance. Defaults to 1.
<code>length.out</code>	an optional integer specifying the length of the sequence of distances to be used for calculating the semi-variogram, when <code>distance = NULL</code> . Defaults to 50.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a data frame with columns `variog` and `dist` representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class `Variogram`.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

```

---

`Variogram.corGaus` *Calculate Semi-variogram for a corGaus Object*

---

**Description**

This method function calculates the semi-variogram values corresponding to the Gaussian correlation model, using the estimated coefficients corresponding to `object`, at the distances defined by `distance`.

**Usage**

```
## S3 method for class 'corGaus':
Variogram(object, distance, sig2, length.out, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>corGaus</code> , representing an Gaussian spatial correlation structure.
<code>distance</code>	an optional numeric vector with the distances at which the semi-variogram is to be calculated. Defaults to <code>NULL</code> , in which case a sequence of length <code>length.out</code> between the minimum and maximum values of <code>getCovariate(object)</code> is used.
<code>sig2</code>	an optional numeric value representing the process variance. Defaults to 1.
<code>length.out</code>	an optional integer specifying the length of the sequence of distances to be used for calculating the semi-variogram, when <code>distance = NULL</code> . Defaults to 50.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a data frame with columns `variog` and `dist` representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class `Variogram`.

Variogram.corLin     *Calculate Semi-variogram for a corLin Object*

---

**Description**

This method function calculates the semi-variogram values corresponding to the Linear correlation model, using the estimated coefficients corresponding to `object`, at the distances defined by `distance`.

**Usage**

```
## S3 method for class 'corLin':
Variogram(object, distance, sig2, length.out, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>corLin</code> , representing an Linear spatial correlation structure.
<code>distance</code>	an optional numeric vector with the distances at which the semi-variogram is to be calculated. Defaults to <code>NULL</code> , in which case a sequence of length <code>length.out</code> between the minimum and maximum values of <code>getCovariate(object)</code> is used.
<code>sig2</code>	an optional numeric value representing the process variance. Defaults to 1.
<code>length.out</code>	an optional integer specifying the length of the sequence of distances to be used for calculating the semi-variogram, when <code>distance = NULL</code> . Defaults to 50.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a data frame with columns `variog` and `dist` representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class `Variogram`.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

```

---

`Variogram.corRatio` *Calculate Semi-variogram for a corRatio Object*

---

**Description**

This method function calculates the semi-variogram values corresponding to the Rational Quadratic correlation model, using the estimated coefficients corresponding to `object`, at the distances defined by `distance`.

**Usage**

```
## S3 method for class 'corRatio':
Variogram(object, distance, sig2, length.out, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>corRatio</code> , representing an Rational Quadratic spatial correlation structure.
<code>distance</code>	an optional numeric vector with the distances at which the semi-variogram is to be calculated. Defaults to <code>NULL</code> , in which case a sequence of length <code>length.out</code> between the minimum and maximum values of <code>getCovariate(object)</code> is used.
<code>sig2</code>	an optional numeric value representing the process variance. Defaults to 1.
<code>length.out</code>	an optional integer specifying the length of the sequence of distances to be used for calculating the semi-variogram, when <code>distance = NULL</code> . Defaults to 50.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a data frame with columns `variog` and `dist` representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class `Variogram`.

---

Variogram.corSpatial

*Calculate Semi-variogram for a corSpatial Object*

---

**Description**

This method function calculates the semi-variogram values corresponding to the model defined in `FUN`, using the estimated coefficients corresponding to `object`, at the distances defined by `distance`.

**Usage**

```
## S3 method for class 'corSpatial':
Variogram(object, distance, sig2, length.out, FUN, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>corSpatial</code> , representing spatial correlation structure.
<code>distance</code>	an optional numeric vector with the distances at which the semi-variogram is to be calculated. Defaults to <code>NULL</code> , in which case a sequence of length <code>length.out</code> between the minimum and maximum values of <code>getCovariate(object)</code> is used.
<code>sig2</code>	an optional numeric value representing the process variance. Defaults to 1.
<code>length.out</code>	an optional integer specifying the length of the sequence of distances to be used for calculating the semi-variogram, when <code>distance = NULL</code> . Defaults to 50.

FUN a function of two arguments, the distance and the range corresponding to object, specifying the semi-variogram model.

... some methods for this generic require additional arguments. None are used in this method.

### Value

a data frame with columns `variog` and `dist` representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class `Variogram`.

```

---

Variogram.corSpher *Calculate Semi-variogram for a corSpher Object*

---

### Description

This method function calculates the semi-variogram values corresponding to the Spherical correlation model, using the estimated coefficients corresponding to `object`, at the distances defined by `distance`.

### Usage

```
## S3 method for class 'corSpher':
Variogram(object, distance, sig2, length.out, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>corSpher</code> , representing an Spherical spatial correlation structure.
<code>distance</code>	an optional numeric vector with the distances at which the semi-variogram is to be calculated. Defaults to <code>NULL</code> , in which case a sequence of length <code>length.out</code> between the minimum and maximum values of <code>getCovariate(object)</code> is used.
<code>sig2</code>	an optional numeric value representing the process variance. Defaults to 1.
<code>length.out</code>	an optional integer specifying the length of the sequence of distances to be used for calculating the semi-variogram, when <code>distance = NULL</code> . Defaults to 50.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

Variogram(cs1)[1:10,]
```

---

Variogram.default *Calculate Semi-variogram*

---

**Description**

This method function calculates the semi-variogram for an arbitrary vector `object`, according to the distances in `distance`. For each pair of elements  $x, y$  in `object`, the corresponding semi-variogram is  $(x - y)^2/2$ . The semi-variogram is useful for identifying and modeling spatial correlation structures in observations with constant expectation and constant variance.

**Usage**

```
## Default S3 method:
Variogram(object, distance, ...)
```

**Arguments**

<code>object</code>	a numeric vector with the values to be used for calculating the semi-variogram, usually a residual vector from a fitted model.
<code>distance</code>	a numeric vector with the pairwise distances corresponding to the elements of <code>object</code> . The order of the elements in <code>distance</code> must correspond to the pairs $(1, 2)$ , $(1, 3)$ , ..., $(n-1, n)$ , with $n$ representing the length of <code>object</code> , and must have length $n(n-1)/2$ .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a data frame with columns `variog` and `dist` representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class `Variogram`.

**Author(s)**

Jose Pinheiro <Jose.Pinheiro@pharma.novartis.com> and Douglas Bates <bates@stat.wisc.edu>

**References**

Cressie, N.A.C. (1993), "Statistics for Spatial Data", J. Wiley & Sons.

**See Also**

[Variogram](#), [Variogram.gls](#), [Variogram.lme](#), [plot.Variogram](#)

**Examples**

```
## Not run:
fm1 <- lm(follicles ~ sin(2 * pi * Time) + cos(2 * pi * Time), Ovary,
         subset = Mare == 1)
Variogram(resid(fm1), dist(1:29))[1:10,]

## End(Not run)
```

---

Variogram.gls

*Calculate Semi-variogram for Residuals from a gls Object*

---

**Description**

This method function calculates the semi-variogram for the residuals from a `gls` fit. The semi-variogram values are calculated for pairs of residuals within the same group level, if a grouping factor is present. If `collapse` is different from "none", the individual semi-variogram values are collapsed using either a robust estimator (`robust = TRUE`) defined in Cressie (1993), or the average of the values within the same distance interval. The semi-variogram is useful for modeling the error term correlation structure.

**Usage**

```
## S3 method for class 'gls':
Variogram(object, distance, form, resType, data,
          na.action, maxDist, length.out, collapse, nint, breaks,
          robust, metric, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>gls</code> , representing a generalized least squares fitted model.
<code>distance</code>	an optional numeric vector with the distances between residual pairs. If a grouping variable is present, only the distances between residual pairs within the same group should be given. If missing, the distances are calculated based on the values of the arguments <code>form</code> , <code>data</code> , and <code>metric</code> , unless <code>object</code> includes a <code>corSpatial</code> element, in which case the associated covariate (obtained with the <code>getCovariate</code> method) is used.
<code>form</code>	an optional one-sided formula specifying the covariate(s) to be used for calculating the distances between residual pairs and, optionally, a grouping factor for partitioning the residuals (which must appear to the right of a <code> </code> operator in <code>form</code> ). Default is <code>~1</code> , implying that the observation order within the groups is used to obtain the distances.
<code>resType</code>	an optional character string specifying the type of residuals to be used. If <code>"response"</code> , the <code>"raw"</code> residuals (observed - fitted) are used; else, if <code>"pearson"</code> , the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if <code>"normalized"</code> , the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to <code>"pearson"</code> .
<code>data</code>	an optional data frame in which to interpret the variables in <code>form</code> . By default, the same data used to fit <code>object</code> is used.
<code>na.action</code>	a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes an error message to be printed and the function to terminate, if there are any incomplete observations.
<code>maxDist</code>	an optional numeric value for the maximum distance used for calculating the semi-variogram between two residuals. By default all residual pairs are included.
<code>length.out</code>	an optional integer value. When <code>object</code> includes a <code>corSpatial</code> element, its semi-variogram values are calculated and this argument is used as the <code>length.out</code> argument to the corresponding <code>Variogram</code> method. Defaults to 50.
<code>collapse</code>	an optional character string specifying the type of collapsing to be applied to the individual semi-variogram values. If equal to <code>"quantiles"</code> , the semi-variogram values are split according to quantiles of the distance distribution, with equal number of observations per group, with possibly varying distance interval lengths. Else, if <code>"fixed"</code> , the semi-variogram values are divided according to distance intervals of equal lengths, with possibly different number of observations per interval. Else, if <code>"none"</code> , no collapsing is used and the individual semi-variogram values are returned. Defaults to <code>"quantiles"</code> .

nint	an optional integer with the number of intervals to be used when collapsing the semi-variogram values. Defaults to 20.
robust	an optional logical value specifying if a robust semi-variogram estimator should be used when collapsing the individual values. If TRUE the robust estimator is used. Defaults to FALSE.
breaks	an optional numeric vector with the breakpoints for the distance intervals to be used in collapsing the semi-variogram values. If not missing, the option specified in collapse is ignored.
metric	an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".
...	some methods for this generic require additional arguments. None are used in this method.

### Value

a data frame with columns `variog` and `dist` representing, respectively, the semi-variogram values and the corresponding distances. If the semi-variogram values are collapsed, an extra column, `n.pairs`, with the number of residual pairs used in each semi-variogram calculation, is included in the returned data frame. If `object` includes a `corSpatial` element, a data frame with its corresponding semi-variogram is included in the returned value, as an attribute "modelVariog". The returned value inherits from class `Variogram`.

## End(Not run)
```

Variogram.lme

*Calculate Semi-variogram for Residuals from an lme Object***Description**

This method function calculates the semi-variogram for the within-group residuals from an `lme` fit. The semi-variogram values are calculated for pairs of residuals within the same group. If `collapse` is different from "none", the individual semi-variogram values are collapsed using either a robust estimator (`robust = TRUE`) defined in Cressie (1993), or the average of the values within the same distance interval. The semi-variogram is useful for modeling the error term correlation structure.

**Usage**

```
## S3 method for class 'lme':
Variogram(object, distance, form, resType, data,
          na.action, maxDist, length.out, collapse, nint, breaks,
          robust, metric, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>lme</code> , representing a fitted linear mixed-effects model.
<code>distance</code>	an optional numeric vector with the distances between residual pairs. If a grouping variable is present, only the distances between residual pairs within the same group should be given. If missing, the distances are calculated based on the values of the arguments <code>form</code> , <code>data</code> , and <code>metric</code> , unless <code>object</code> includes a <code>corSpatial</code> element, in which case the associated covariate (obtained with the <code>getCovariate</code> method) is used.
<code>form</code>	an optional one-sided formula specifying the covariate(s) to be used for calculating the distances between residual pairs and, optionally, a grouping factor for partitioning the residuals (which must appear to the right of a <code> </code> operator in <code>form</code> ). Default is <code>~1</code> , implying that the observation order within the groups is used to obtain the distances.
<code>resType</code>	an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".
<code>data</code>	an optional data frame in which to interpret the variables in <code>form</code> . By default, the same data used to fit <code>object</code> is used.
<code>na.action</code>	a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes an error message to be printed and the function to terminate, if there are any incomplete observations.
<code>maxDist</code>	an optional numeric value for the maximum distance used for calculating the semi-variogram between two residuals. By default all residual pairs are included.

<code>length.out</code>	an optional integer value. When <code>object</code> includes a <code>corSpatial</code> element, its semi-variogram values are calculated and this argument is used as the <code>length.out</code> argument to the corresponding <code>Variogram</code> method. Defaults to 50.
<code>collapse</code>	an optional character string specifying the type of collapsing to be applied to the individual semi-variogram values. If equal to <code>"quantiles"</code> , the semi-variogram values are split according to quantiles of the distance distribution, with equal number of observations per group, with possibly varying distance interval lengths. Else, if <code>"fixed"</code> , the semi-variogram values are divided according to distance intervals of equal lengths, with possibly different number of observations per interval. Else, if <code>"none"</code> , no collapsing is used and the individual semi-variogram values are returned. Defaults to <code>"quantiles"</code> .
<code>nint</code>	an optional integer with the number of intervals to be used when collapsing the semi-variogram values. Defaults to 20.
<code>robust</code>	an optional logical value specifying if a robust semi-variogram estimator should be used when collapsing the individual values. If <code>TRUE</code> the robust estimator is used. Defaults to <code>FALSE</code> .
<code>breaks</code>	an optional numeric vector with the breakpoints for the distance intervals to be used in collapsing the semi-variogram values. If not missing, the option specified in <code>collapse</code> is ignored.
<code>metric</code>	an optional character string specifying the distance metric to be used. The currently available options are <code>"euclidean"</code> for the root sum-of-squares of distances; <code>"maximum"</code> for the maximum difference; and <code>"manhattan"</code> for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to <code>"euclidean"</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

### Value

a data frame with columns `variog` and `dist` representing, respectively, the semi-variogram values and the corresponding distances. If the semi-variogram values are collapsed, an extra column, `n.pairs`, with the number of residual pairs used in each semi-variogram calculation, is included in the returned data frame. If `object` includes a `corSpatial` element, a data frame with its corresponding semi-variogram is included in the returned value, as an attribute `"modelVariog"`. The returned value inherits from class `Variogram`.

Variogram(fml, form = ~ Time | Rat, nint = 10, robust = TRUE)
```

varPower

*Power Variance Function***Description**

This function is a constructor for the `varPower` class, representing a power variance function structure. Letting  $v$  denote the variance covariate and  $\sigma^2(v)$  denote the variance function evaluated at  $v$ , the power variance function is defined as  $\sigma^2(v) = |v|^{2\theta}$ , where  $\theta$  is the variance function coefficient. When a grouping factor is present, a different  $\theta$  is used for each factor level.

**Usage**

```
varPower(value, form, fixed)
```

**Arguments**

value	an optional numeric vector, or list of numeric values, with the variance function coefficients. Value must have length one, unless a grouping factor is specified in <code>form</code> . If <code>value</code> has length greater than one, it must have names which identify its elements to the levels of the grouping factor defined in <code>form</code> . If a grouping factor is present in <code>form</code> and <code>value</code> has length one, its value will be assigned to all grouping levels. Default is <code>numeric(0)</code> , which results in a vector of zeros of appropriate length being assigned to the coefficients when object is initialized (corresponding to constant variance equal to one).
form	an optional one-sided formula of the form <code>~ v</code> , or <code>~ v   g</code> , specifying a variance covariate <code>v</code> and, optionally, a grouping factor <code>g</code> for the coefficients. The variance covariate must evaluate to a numeric vector and may involve expressions using <code>"."</code> , representing a fitted model object from which fitted values ( <code>fitted(.)</code> ) and residuals ( <code>resid(.)</code> ) can be extracted (this allows the variance covariate to be updated during the optimization of an object function). When a grouping factor is present in <code>form</code> , a different coefficient value is used for each of its levels. Several grouping variables may be simultaneously specified, separated by the <code>*</code> operator, like in <code>~ v   g1 * g2 * g3</code> . In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to <code>~ fitted(.)</code> representing a variance covariate given by the fitted values of a fitted model object and no grouping factor.
fixed	an optional numeric vector, or list of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. If a grouping factor is specified in <code>form</code> , <code>fixed</code> must have names identifying which coefficients are to be fixed. Coefficients included in <code>fixed</code> are not allowed to vary during the optimization of an objective function. Defaults to <code>NULL</code> , corresponding to no fixed coefficients.

**Value**

a `varPower` object representing a power variance function structure, also inheriting from class `varFunc`.

varWeights

*Extract Variance Function Weights*

---

**Description**

The inverse of the standard deviations corresponding to the variance function structure represented by `object` are returned.

**Usage**

```
varWeights(object)
```

**Arguments**

`object` an object inheriting from class `varFunc`, representing a variance function structure.

**Value**

if `object` has a `weights` attribute, its value is returned; else `NULL` is returned.

varWeights.glsStruct

*Variance Weights for glsStruct Object*

---

## Description

If `object` includes a `varStruct` component, the inverse of the standard deviations of the variance function structure represented by the corresponding `varFunc` object are returned; else, a vector of ones of length equal to the number of observations in the data frame used to fit the associated linear model is returned.

## Usage

```
## S3 method for class 'glsStruct':
varWeights(object)
```

## Arguments

`object` an object inheriting from class `glsStruct`, representing a list of linear model components, such as `corStruct` and `varFunc` objects.

## Value

if `object` includes a `varStruct` component, a vector with the corresponding variance weights; else, or a vector of ones.

[.pdMat

*Subscript a pdMat Object***Description**

This method function extracts sub-matrices from the positive-definite matrix represented by `x`.

**Usage**

```
## S3 method for class 'pdMat':
x[i, j, drop = TRUE]
## S3 replacement method for class 'pdMat':
x[i, j] <- value
```

**Arguments**

<code>x</code>	an object inheriting from class <code>pdMat</code> representing a positive-definite matrix.
<code>i, j</code>	optional subscripts applying respectively to the rows and columns of the positive-definite matrix represented by <code>object</code> . When <code>i</code> ( <code>j</code> ) is omitted, all rows (columns) are extracted.
<code>drop</code>	a logical value. If <code>TRUE</code> , single rows or columns are converted to vectors. If <code>FALSE</code> the returned value retains its matrix representation.
<code>value</code>	a vector, or matrix, with the replacement values for the relevant piece of the matrix represented by <code>x</code> .

**Value**

if `i` and `j` are identical, the returned value will be `pdMat` object with the same class as `x`. Otherwise, the returned value will be a matrix. In the case a single row (or column) is selected, the returned value may be converted to a vector, according to the rules above.

pd1[1, , drop = FALSE]
pd1[1:2, 1:2] <- 3 * diag(2)
```

## Chapter 20

# The `nnet` package

---

`class.ind`

*Generates Class Indicator Matrix from a Factor*

---

### Description

Generates a class indicator function from a given factor.

### Usage

```
class.ind(cl)
```

### Arguments

`cl` factor or vector of classes for cases.

### Value

a matrix which is zero except for the column corresponding to the class.

### References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

### Examples

```
# The function is currently defined as
class.ind <- function(cl)
{
  n <- length(cl)
  cl <- as.factor(cl)
  x <- matrix(0, n, length(levels(cl)) )
  x[(1:n) + n*(unclass(cl)-1)] <- 1
  dimnames(x) <- list(names(cl), levels(cl))
  x
}
```

---

multinom

*Fit Multinomial Log-linear Models*

---

### Description

Fits multinomial log-linear models via neural networks.

### Usage

```
multinom(formula, data, weights, subset, na.action,
         contrasts = NULL, Hess = FALSE, summ = 0, censored = FALSE,
         model = FALSE, ...)
```

### Arguments

<code>formula</code>	a formula expression as for regression models, of the form <code>response ~ predictors</code> . The response should be a factor or a matrix with <code>K</code> columns, which will be interpreted as counts for each of <code>K</code> classes. A log-linear model is fitted, with coefficients zero for the first class. An offset can be included: it should be a numeric matrix with <code>K</code> columns if the response is either a matrix with <code>K</code> columns or a factor with <code>K &gt; 2</code> classes, or a numeric vector for a response factor with 2 levels. See the documentation of <code>formula()</code> for other details.
<code>data</code>	an optional data frame in which to interpret the variables occurring in <code>formula</code> .
<code>weights</code>	optional case weights in fitting.
<code>subset</code>	expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.
<code>na.action</code>	a function to filter missing data.
<code>contrasts</code>	a list of contrasts to be used for some or all of the factors appearing as variables in the model formula.
<code>Hess</code>	logical for whether the Hessian (the observed/expected information matrix) should be returned.
<code>summ</code>	integer; if non-zero summarize by deleting duplicate rows and adjust weights. Methods 1 and 2 differ in speed (2 uses C); method 3 also combines rows with the same X and different Y, which changes the baseline for the deviance.
<code>censored</code>	If Y is a matrix with <code>K &gt; 2</code> columns, interpret the entries as one for possible classes, zero for impossible classes, rather than as counts.
<code>model</code>	logical. If true, the model frame is saved as component <code>model</code> of the returned object.
<code>...</code>	additional arguments for <code>nnet</code>

### Details

`multinom` calls `nnet`. The variables on the rhs of the formula should be roughly scaled to [0,1] or the fit will be slow or may not converge at all.

**Value**

A `nnet` object with additional components:

deviance	the residual deviance, compared to the full saturated model (that explains individual observations exactly). Also, minus twice log-likelihood.
edf	the (effective) number of degrees of freedom used by the model
AIC	the AIC for this fit.
Hessian	(if <code>Hess</code> is true).
model	(if <code>model</code> is true).

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

**See Also**

  0.7555234  1.343648  1.913213  0.6802007 -0.4363238  0.1789888

Residual Deviance: 195.4755
AIC: 217.4755

## End(Not run)
```

---

nnet

*Fit Neural Networks*

---

**Description**

Fit single-hidden-layer neural network, possibly with skip-layer connections.

**Usage**

```
nnet(x, ...)

## S3 method for class 'formula':
nnet(formula, data, weights, ...,
      subset, na.action, contrasts = NULL)

## Default S3 method:
nnet(x, y, weights, size, Wts, mask,
      linout = FALSE, entropy = FALSE, softmax = FALSE,
      censored = FALSE, skip = FALSE, rang = 0.7, decay = 0,
      maxit = 100, Hess = FALSE, trace = TRUE, MaxNWts = 1000,
      abstol = 1.0e-4, reltol = 1.0e-8, ...)
```

**Arguments**

<code>formula</code>	A formula of the form <code>class ~ x1 + x2 + ...</code>
<code>x</code>	matrix or data frame of <code>x</code> values for examples.
<code>y</code>	matrix or data frame of target values for examples.
<code>weights</code>	(case) weights for each example – if missing defaults to 1.
<code>size</code>	number of units in the hidden layer. Can be zero if there are skip-layer units.
<code>data</code>	Data frame from which variables specified in <code>formula</code> are preferentially to be taken.
<code>subset</code>	An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)
<code>na.action</code>	A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is <code>na.omit</code> , which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.)
<code>contrasts</code>	a list of contrasts to be used for some or all of the factors appearing as variables in the model formula.
<code>Wts</code>	initial parameter vector. If missing chosen at random.
<code>mask</code>	logical vector indicating which parameters should be optimized (default all).
<code>linout</code>	switch for linear output units. Default logistic output units.
<code>entropy</code>	switch for entropy (= maximum conditional likelihood) fitting. Default by least-squares.
<code>softmax</code>	switch for softmax (log-linear model) and maximum conditional likelihood fitting. <code>linout</code> , <code>entropy</code> , <code>softmax</code> and <code>censored</code> are mutually exclusive.
<code>censored</code>	A variant on <code>softmax</code> , in which non-zero targets mean possible classes. Thus for <code>softmax</code> a row of (0, 1, 1) means one example each of classes 2 and 3, but for <code>censored</code> it means one example whose class is only known to be 2 or 3.
<code>skip</code>	switch to add skip-layer connections from input to output.
<code>rang</code>	Initial random weights on <code>[-rang, rang]</code> . Value about 0.5 unless the inputs are large, in which case it should be chosen so that <code>rang * max( x )</code> is about 1.
<code>decay</code>	parameter for weight decay. Default 0.
<code>maxit</code>	maximum number of iterations. Default 100.

Hess	If true, the Hessian of the measure of fit at the best set of weights found is returned as component <code>Hessian</code> .
trace	switch for tracing optimization. Default TRUE.
MaxNWts	The maximum allowable number of weights. There is no intrinsic limit in the code, but increasing <code>MaxNWts</code> will probably allow fits that are very slow and time-consuming.
abstol	Stop if the fit criterion falls below <code>abstol</code> , indicating an essentially perfect fit.
reltol	Stop if the optimizer is unable to reduce the fit criterion by a factor of at least <code>1 - reltol</code> .
...	arguments passed to or from other methods.

### Details

If the response in `formula` is a factor, an appropriate classification network is constructed; this has one output and entropy fit if the number of levels is two, and a number of outputs equal to the number of classes and a softmax output stage for more levels. If the response is not a factor, it is passed on unchanged to `nnet.default`.

Optimization is done via the BFGS method of `optim`.

### Value

object of class "nnet" or "nnet.formula". Mostly internal structure, but has components

<code>wts</code>	the best set of weights found
<code>value</code>	value of fitting criterion plus weight decay term.
<code>fitted.values</code>	the fitted values for the training data.
<code>residuals</code>	the residuals for the training data.
<code>convergence</code>	1 if the maximum number of iterations was reached, otherwise 0.

  decay = 5e-4, maxit = 200)
table(ird$species[-samp], predict(ir.nn2, ird[-samp,], type = "class"))

```

---

nnetHess

*Evaluates Hessian for a Neural Network*

---

### Description

Evaluates the Hessian (matrix of second derivatives) of the specified neural network. Normally called via argument `Hess=TRUE` to `nnet` or via `vcov.multinom`.

### Usage

```
nnetHess(net, x, y, weights)
```

### Arguments

<code>net</code>	object of class <code>nnet</code> as returned by <code>nnet</code> .
<code>x</code>	training data.
<code>y</code>	classes for training data.
<code>weights</code>	the (case) weights used in the <code>nnet</code> fit.

### Value

square symmetric matrix of the Hessian evaluated at the weights stored in the net.

```

---

predict.nnet                      *Predict New Examples by a Trained Neural Net*

---

## Description

Predict new examples by a trained neural net.

## Usage

```
## S3 method for class 'nnet':
predict(object, newdata, type = c("raw", "class"), ...)
```

## Arguments

object	an object of class nnet as returned by nnet.
newdata	matrix or data frame of test examples. A vector is considered to be a row vector comprising a single case.
type	Type of output
...	arguments passed to or from other methods.

## Details

This function is a method for the generic function `predict()` for class "nnet". It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.nnet(x)` regardless of the class of the object.

## Value

If `type = "raw"`, the matrix of values returned by the trained network; if `type = "class"`, the corresponding class (which is probably only useful if the net was generated by `nnet.formula`).

## References

Ripley, B. D. (1996) *Pattern Recognition and Neural Networks*. Cambridge.  
 Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

  true <- max.col(true)
```

```

      cres <- max.col(pred)
      table(true, cres)
    }
test.cl(targets[-samp,], predict(ir1, ir[-samp,]))

# or
ird <- data.frame(rbind(iris3[,1], iris3[,2], iris3[,3]),
  species=factor(c(rep("s",50), rep("c", 50), rep("v", 50))))
ir.nn2 <- nnet(species ~ ., data = ird, subset = samp, size = 2, rang = 0.1,
  decay = 5e-4, maxit = 200)
table(ird$species[-samp], predict(ir.nn2, ird[-samp,], type = "class"))

```

---

which.is.max

*Find Maximum Position in Vector*

---

### Description

Find the maximum position in a vector, breaking ties at random.

### Usage

```
which.is.max(x)
```

### Arguments

x                    a vector

### Details

Ties are broken at random.

### Value

index of a maximal value.

### References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

### See Also

[max.col](#), [which.max](#) which takes the first of ties.

### Examples

```

## Not run:
pred <- predict(nnet, test)
table(true, apply(pred,1,which.is.max))

## End(Not run)

```

## Chapter 21

# The rpart package

---

`car.test.frame`      *Automobile Data from 'Consumer Reports' 1990*

---

### Description

The `car.test.frame` data frame has 60 rows and 8 columns, giving data on makes of cars taken from the April, 1990 issue of *Consumer Reports*. This is part of a larger dataset, some columns of which are given in [cu.summary](#).

### Usage

```
car.test.frame
```

### Format

This data frame contains the following columns:

`Price` a numeric vector giving the list price in US dollars of a standard model

`Country of origin`, a factor with levels France Germany Japan Japan/USA Korea Mexico Sweden USA

`Reliability` a numeric vector coded 1 to 5.

`Mileage` fuel consumption miles per US gallon, as tested.

`Type` a factor with levels Compact Large Medium Small Sporty Van

`Weight` kerb weight in pounds.

`Disp.` the engine capacity (displacement) in litres.

`HP` the net horsepower of the vehicle.

### Source

```
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
summary(z.auto)
```

---

cu.summary

*Automobile Data from 'Consumer Reports' 1990*

---

**Description**

The `cu.summary` data frame has 117 rows and 5 columns, giving data on makes of cars taken from the April, 1990 issue of *Consumer Reports*.

**Usage**

```
cu.summary
```

**Format**

This data frame contains the following columns:

`Price` a numeric vector giving the list price in US dollars of a standard model

`Country of origin`, a factor with levels Brazil England France Germany Japan  
Japan/USA Korea Mexico Sweden USA

`Reliability` an ordered factor with levels Much worse < worse < average < better <  
Much better

`Mileage` fuel consumption miles per US gallon, as tested.

`Type` a factor with levels Compact Large Medium Small Sporty Van

**Source**

*Consumer Reports*, April, 1990, pp. 235–288 quoted in

kyphosis

*Data on Children who have had Corrective Spinal Surgery***Description**

The `kyphosis` data frame has 81 rows and 4 columns. representing data on children who have had corrective spinal surgery

**Usage**

```
kyphosis
```

**Format**

This data frame contains the following columns:

`Kyphosis` a factor with levels `absent` `present` indicating if a kyphosis (a type of deformation) was present after the operation.

`Age` in months

`Number` the number of vertebrae involved

`Start` the number of the first (topmost) vertebra operated on.

**Source**

John M. Chambers and Trevor J. Hastie eds. (1992) *Statistical Models in S*, Wadsworth and Brooks/Cole, Pacific Grove, CA 1992.

**Examples**

```
fit <- rpart(Kyphosis ~ Age + Number + Start, data=kyphosis)
fit2 <- rpart(Kyphosis ~ Age + Number + Start, data=kyphosis,
             parms=list(prior=c(.65,.35), split='information'))
fit3 <- rpart(Kyphosis ~ Age + Number + Start, data=kyphosis,
             control=rpart.control(cp=.05))
par(mfrow=c(1,2))
plot(fit)
text(fit, use.n=TRUE)
plot(fit2)
text(fit2, use.n=TRUE)
```

labels.rpart

*Create Split Labels For an Rpart Object***Description**

This function provides labels for the branches of an `rpart` tree.

**Usage**

```
## S3 method for class 'rpart':
labels(object, digits=4, minlength=1L, pretty, collapse=TRUE, ...)
```

**Arguments**

object	fitted model object of class <code>rpart</code> . This is assumed to be the result of some function that produces an object with the same named components as that returned by the <code>rpart</code> function.
digits	the number of digits to be used for numeric values. All of the <code>rpart</code> functions that call labels explicitly set this value, with <code>options("digits")</code> as the default.
minlength	the minimum length for abbreviation of character or factor variables. If 0 no abbreviation is done; if 1 then single letters are used with "a" for the first level, "b" for the second and so on. If the value is greater than 1, the <code>abbreviate</code> function is used.
pretty	an argument included for backwards compatibility: <code>pretty=0</code> implies <code>minlength=0</code> , <code>pretty=NULL</code> implies <code>minlength=1</code> , and <code>pretty=TRUE</code> implies <code>minlength=4</code> .
collapse	logical. The returned set of labels is always of the same length as the number of nodes in the tree. If <code>collapse=TRUE</code> (default), the returned value is a vector of labels for the branch leading into each node, with "root" as the label for the top node. If <code>FALSE</code> , the returned value is a two column matrix of labels for the left and right branches leading out from each node, with "leaf" as the branch labels for terminal nodes.
...	optional arguments to <code>abbreviate</code> .

**Value**

Vector of split labels (`collapse=TRUE`) or matrix of left and right splits (`collapse=FALSE`) for the supplied `rpart` object. This function is called by printing methods for `rpart` and is not intended to be called directly by the users.

**See Also**

[abbreviate](#)

---

`meanvar.rpart`

*Mean-Variance Plot for an Rpart Object*

---

**Description**

Creates a plot on the current graphics device of the deviance of the node divided by the number of observations at the node. Also returns the node number.

**Usage**

```
meanvar(tree, ...)
```

```
## S3 method for class 'rpart':
meanvar(tree, xlab="ave(y)", ylab="ave(deviance)", ...)
```

**Arguments**

tree	fitted model object of class <code>rpart</code> . This is assumed to be the result of some function that produces an object with the same named components as that returned by the <code>rpart</code> function.
xlab	x-axis label for the plot.
ylab	y-axis label for the plot.
...	additional graphical parameters may be supplied as arguments to this function.

**Value**

an invisible list containing the following vectors is returned.

x	fitted value at terminal nodes ( <code>yval</code> ).
y	deviance of node divided by number of observations at node.
label	node number.

**Side Effects**

a plot is put on the current graphics device.

**See Also**

[plot.rpart](#).

**Examples**

```
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
meanvar(z.auto, log='xy')
```

---

na.rpart

*Handles Missing Values in an Rpart Object*

---

**Description**

Handles missing values in an `rpart` object.

**Usage**

```
na.rpart(x)
```

**Arguments**

x	a model frame.
---	----------------

**Details**

Internal function that handles missing values when calling the function `rpart`.

---

path.rpart                      *Follow Paths to Selected Nodes of an Rpart Object*

---

### Description

Returns a names list where each element contains the splits on the path from the root to the selected nodes.

### Usage

```
path.rpart(tree, nodes, pretty=0, print.it=TRUE)
```

### Arguments

tree	fitted model object of class <code>rpart</code> . This is assumed to be the result of some function that produces an object with the same named components as that returned by the <code>rpart</code> function.
nodes	an integer vector containing indices (node numbers) of all nodes for which paths are desired. If missing, user selects nodes as described below.
pretty	an integer denoting the extent to which factor levels in split labels will be abbreviated. A value of (0) signifies no abbreviation. A <code>NULL</code> , the default, signifies using elements of letters to represent the different factor levels.
print.it	Logical. Denotes whether paths will be printed out as nodes are interactively selected. Irrelevant if <code>nodes</code> argument is supplied.

### Details

The function has a required argument as an `rpart` object and a list of nodes as optional arguments. Omitting a list of nodes will cause the function to wait for the user to select nodes from the dendrogram. It will return a list, with one component for each node specified or selected. The component contains the sequence of splits leading to that node. In the graphical interaction, the individual paths are printed out as nodes are selected.

### Value

A named (by node) list, each element of which contains all the splits on the path from the root to the specified or selected nodes.

### Graphical Interaction

A dendrogram of the `rpart` object is expected to be visible on the graphics device, and a graphics input device (e.g. a mouse) is required. Clicking (the selection button) on a node selects that node. This process may be repeated any number of times. Clicking the exit button will stop the selection process and return the list of paths.

### References

This function was modified from `path.tree` in `S`.

fit <- rpart(Kyphosis ~ Age + Number + Start, data=kyphosis)
summary(fit)
path.rpart(fit, node=c(11, 22))
```

---

plot.rpart	<i>Plot an Rpart Object</i>
------------	-----------------------------

---

**Description**

Plots an rpart object on the current graphics device.

**Usage**

```
## S3 method for class 'rpart':
plot(x, uniform=FALSE, branch=1, compress=FALSE, nspace,
      margin=0, minbranch=.3, ...)
```

**Arguments**

x	a fitted object of class <code>rpart</code> , containing a classification, regression, or rate tree.
uniform	if <code>TRUE</code> , uniform vertical spacing of the nodes is used; this may be less cluttered when fitting a large plot onto a page. The default is to use a non-uniform spacing proportional to the error in the fit.
branch	controls the shape of the branches from parent to child node. Any number from 0 to 1 is allowed. A value of 1 gives square shouldered branches, a value of 0 give V shaped branches, with other values being intermediate.
compress	if <code>FALSE</code> , the leaf nodes will be at the horizontal plot coordinates of <code>1:nleaves</code> . If <code>TRUE</code> , the routine attempts a more compact arrangement of the tree. The compaction algorithm assumes <code>uniform=TRUE</code> ; surprisingly, the result is usually an improvement even when that is not the case.
nspace	the amount of extra space between a node with children and a leaf, as compared to the minimal space between leaves. Applies to compressed trees only. The default is the value of <code>branch</code> .
margin	an extra percentage of white space to leave around the borders of the tree. (Long labels sometimes get cut off by the default computation).
minbranch	set the minimum length for a branch to <code>minbranch</code> times the average branch length. This parameter is ignored if <code>uniform=TRUE</code> . Sometimes a split will give very little improvement, or even (in the classification case) no improvement at all. A tree with branch lengths strictly proportional to improvement leaves no room to squeeze in node labels.
...	arguments to be passed to or from other methods.

**Details**

This function is a method for the generic function `plot`, for objects of class `rpart`. The y-coordinate of the top node of the tree will always be 1.

**Value**

The coordinates of the nodes are returned as a list, with components `x` and `y`.

**Side Effects**

An unlabeled plot is produced on the current graphics device.

**See Also**

`rpart`, `text.rpart`

**Examples**

```
fit <- rpart(Price ~ Mileage + Type + Country, cu.summary)
plot(fit, compress=TRUE)
text(fit, use.n=TRUE)
```

---

plotcp

*Plot a Complexity Parameter Table for an Rpart Fit*

---

**Description**

Gives a visual representation of the cross-validation results in an `rpart` object.

**Usage**

```
plotcp(x, minline = TRUE, lty = 3, col = 1,
       upper = c("size", "splits", "none"), ...)
```

**Arguments**

<code>x</code>	an object of class <code>rpart</code>
<code>minline</code>	whether a horizontal line is drawn 1SE above the minimum of the curve.
<code>lty</code>	line type for this line
<code>col</code>	colour for this line
<code>upper</code>	what is plotted on the top axis: the size of the tree (the number of leaves), the number of splits or nothing.
<code>...</code>	additional plotting parameters

**Details**

The set of possible cost-complexity prunings of a tree from a nested set. For the geometric means of the intervals of values of `cp` for which a pruning is optimal, a cross-validation has (usually) been done in the initial construction by `rpart`. The `cpstable` in the fit contains the mean and standard deviation of the errors in the cross-validated prediction against each of the geometric means, and these are plotted by this function. A good choice of `cp` for pruning is often the leftmost value for which the mean lies below the horizontal line.

**Value**

None.

**Side Effects**

A plot is produced on the current graphical device.

**See Also**

[rpart](#), [printcp](#), [rpart.object](#)

---

post.rpart

*PostScript Presentation Plot of an Rpart Object*

---

**Description**

Generates a PostScript presentation plot of an `rpart` object.

**Usage**

```
post(tree, ...)

## S3 method for class 'rpart':
post(tree, title.,
      filename = paste(deparse(substitute(tree)), ".ps", sep = ""),
      digits = getOption("digits") - 3, pretty = TRUE,
      use.n = TRUE, horizontal = TRUE, ...)
```

**Arguments**

<code>tree</code>	fitted model object of class <code>rpart</code> . This is assumed to be the result of some function that produces an object with the same named components as that returned by the <code>rpart</code> function.
<code>title.</code>	a title which appears at the top of the plot. By default, the name of the <code>rpart</code> endpoint is printed out.
<code>filename</code>	ASCII file to contain the output. By default, the name of the file is the name of the object given by <code>rpart</code> (with the suffix <code>.ps</code> added). If <code>filename = ""</code> , the plot appears on the current graphical device.
<code>digits</code>	number of significant digits to include in numerical data.
<code>pretty</code>	an integer denoting the extent to which factor levels will be abbreviated in the character strings defining the splits; (0) signifies no abbreviation of levels. A <code>NULL</code> signifies using elements of letters to represent the different factor levels. The default ( <code>TRUE</code> ) indicates the maximum possible abbreviation.
<code>use.n</code>	Logical. If <code>TRUE</code> (default), adds to label ( <code>\#events level1/\#events level2/etc.</code> for method <code>class</code> , <code>n</code> for method <code>anova</code> , and <code>\#events/n</code> for methods <code>poisson</code> and <code>exp</code> ).
<code>horizontal</code>	Logical. If <code>TRUE</code> (default), plot is horizontal. If <code>FALSE</code> , plot appears as landscape.
<code>...</code>	other arguments to the <code>postscript</code> function.

**Details**

The plot created uses the functions `plot.rpart` and `text.rpart` (with the `fancy` option). The settings were chosen because they looked good to us, but other options may be better, depending on the `rpart` object. Users are encouraged to write their own function containing favorite options.

**Side Effects**

a plot of `rpart` is created using the `postscript` driver, or the current device if `filename = ""`.

**See Also**

[plot.rpart](#), [rpart](#), [text.rpart](#), [abbreviate](#)

**Examples**

```
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
post(z.auto, file = "") # display tree on active device
# now construct postscript version on file "pretty.ps"
# with no title
post(z.auto, file = "pretty.ps", title = " ")
z.hp <- rpart(Mileage ~ Weight + HP, car.test.frame)
post(z.hp)
```

---

`predict.rpart`

*Predictions from a Fitted Rpart Object*

---

**Description**

Returns a vector of predicted responses from a fitted `rpart` object.

**Usage**

```
## S3 method for class 'rpart':
predict(object, newdata = list(),
        type = c("vector", "prob", "class", "matrix"),
        na.action = na.pass, ...)
```

**Arguments**

<code>object</code>	fitted model object of class <code>rpart</code> . This is assumed to be the result of some function that produces an object with the same named components as that returned by the <code>rpart</code> function.
<code>newdata</code>	data frame containing the values at which predictions are required. The predictors referred to in the right side of <code>formula(object)</code> must be present by name in <code>newdata</code> . If missing, the fitted values are returned.
<code>type</code>	character string denoting the type of predicted value returned. If the <code>rpart</code> object is a classification tree, then the default is to return <code>prob</code> predictions, a matrix whose columns are the probability of the first, second, etc. class. (This agrees with the default behavior of <code>tree</code> ). Otherwise, a vector result is returned.

`na.action` a function to determine what should be done with missing values in `newdata`. The default is to pass them down the tree using surrogates in the way selected when the model was built. Other possibilities are `na.omit` and `na.fail`.

`...` further arguments passed to or from other methods.

## Details

This function is a method for the generic function `predict` for class `rpart`. It can be invoked by calling `predict` for an object of the appropriate class, or directly by calling `predict.rpart` regardless of the class of the object.

## Value

A new object is obtained by dropping `newdata` down the object. For factor predictors, if an observation contains a level not used to grow the tree, it is left at the deepest possible node and `frame$yval` at the node is the prediction.

If `type="vector"`:

vector of predicted responses. For regression trees this is the mean response at the node, for Poisson trees it is the estimated response rate, and for classification trees it is the predicted class (as a number).

If `type="prob"`:

(for a classification tree) a matrix of class probabilities.

If `type="matrix"`:

a matrix of the full responses (`frame$yval2` if this exists, otherwise `frame$yval`). For regression trees, this is the mean response, for Poisson trees it is the response rate and the number of events at that node in the fitted tree, and for classification trees it is the concatenation of the predicted class, the class counts at that node in the fitted tree, and the class probabilities.

If `type="class"`:

(for a classification tree) a factor of classifications based on the responses.

## See Also

## Examples

```
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
predict(z.auto)

fit <- rpart(Kyphosis ~ Age + Number + Start, data=kyphosis)
predict(fit, type="prob") # class probabilities (default)
predict(fit, type="vector") # level numbers
predict(fit, type="class") # factor
predict(fit, type="matrix") # level number, class frequencies, probabilities

sub <- c(sample(1:50, 25), sample(51:100, 25), sample(101:150, 25))
fit <- rpart(Species ~ ., data=iris, subset=sub)
fit
table(predict(fit, iris[-sub,], type="class"), iris[-sub, "Species"])
```

---

```
print.rpart
```

*Print an Rpart Object*

---

### Description

This function prints an `rpart` object. It is a method for the generic function `print` of class `rpart`.

### Usage

```
## S3 method for class 'rpart':
print(x, minlength=0, spaces=2, cp, digits= getOption("digits"), ...)
```

### Arguments

<code>x</code>	fitted model object of class <code>rpart</code> . This is assumed to be the result of some function that produces an object with the same named components as that returned by the <code>rpart</code> function.
<code>minlength</code>	Controls the abbreviation of labels: see <a href="#">labels.rpart</a> .
<code>spaces</code>	the number of spaces to indent nodes of increasing depth.
<code>digits</code>	the number of digits of numbers to print.
<code>cp</code>	prune all nodes with a complexity less than <code>cp</code> from the printout. Ignored if unspecified.
<code>...</code>	arguments to be passed to or from other methods.

### Details

This function is a method for the generic function `print` for class `"rpart"`. It can be invoked by calling `print` for an object of the appropriate class, or directly by calling `print.rpart` regardless of the class of the object.

### Side Effects

A semi-graphical layout of the contents of `x$frame` is printed. Indentation is used to convey the tree topology. Information for each node includes the node number, split, size, deviance, and fitted value. For the `"class"` method, the class probabilities are also printed.

## End(Not run)

```

---

printcp

*Displays CP table for Fitted Rpart Object*

---

## Description

Displays the cp table for fitted rpart object.

## Usage

```
printcp(x, digits=getOption("digits") - 2)
```

## Arguments

**x** fitted model object of class `rpart`. This is assumed to be the result of some function that produces an object with the same named components as that returned by the `rpart` function.

**digits** the number of digits of numbers to print.

## Details

Prints a table of optimal prunings based on a complexity parameter.

## See Also

---

prune.rpart	<i>Cost-complexity Pruning of an Rpart Object</i>
-------------	---

---

**Description**

Determines a nested sequence of subtrees of the supplied `rpart` object by recursively snipping off the least important splits, based on the complexity parameter (`cp`).

**Usage**

```
prune(tree, ...)
```

```
## S3 method for class 'rpart':
```

```
prune(tree, cp, ...)
```

**Arguments**

<code>tree</code>	fitted model object of class <code>rpart</code> . This is assumed to be the result of some function that produces an object with the same named components as that returned by the <code>rpart</code> function.
<code>cp</code>	Complexity parameter to which the <code>rpart</code> object will be trimmed.
<code>...</code>	further arguments passed to or from other methods.

**Value**

A new `rpart` object that is trimmed to the value `cp`.

**See Also**

[rpart](#)

**Examples**

```
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
```

```
zp <- prune(z.auto, cp=0.1)
```

```
plot(zp) #plot smaller rpart object
```

---

residuals.rpart	<i>Residuals From a Fitted Rpart Object</i>
-----------------	---

---

**Description**

Method for residuals for an `rpart` object.

**Usage**

```
## S3 method for class 'rpart':
```

```
residuals(object, type = c("usual", "pearson", "deviance"), ...)
```

**Arguments**

object	fitted model object of class "rpart".
type	Indicates the type of residual desired. For regression or anova trees all three residual definitions reduce to $y - \text{fitted}$ . This is the residual returned for user method trees as well. For classification trees the usual residuals are the misclassification losses $L(\text{actual}, \text{predicted})$ where $L$ is the loss matrix. With default losses this residual is 0/1 for correct/incorrect classification. The pearson residual is $(1 - \text{fitted})/\sqrt{\text{fitted}(1 - \text{fitted})}$ and the deviance residual is $\sqrt{\text{minus twice log-arithm of fitted}}$ . For poisson and exp (or survival) trees, the usual residual is the observed - expected number of events. The pearson and deviance residuals are as defined in McCullagh and Nelder.
...	further arguments passed to or from other methods.

**Value**

Vector of residuals of type type from a fitted rpart object.

**References**

McCullagh P. and Nelder, J. A. (1989) *Generalized Linear Models*. London: Chapman and Hall.

**Examples**

```
fit <- rpart(skips ~ Opening + Solder + Mask + PadType + Panel,
            data=solder, method='anova')
summary(residuals(fit))
plot(predict(fit), residuals(fit))
```

---

rpart

*Recursive Partitioning and Regression Trees*

---

**Description**

Fit a rpart model

**Usage**

```
rpart(formula, data, weights, subset, na.action = na.rpart, method,
      model = FALSE, x = FALSE, y = TRUE, parms, control, cost, ...)
```

**Arguments**

formula	a formula, as in the lm function.
data	an optional data frame in which to interpret the variables named in the formula
weights	optional case weights.
subset	optional expression saying that only a subset of the rows of the data should be used in the fit.

<code>na.action</code>	The default action deletes all observations for which <code>y</code> is missing, but keeps those in which one or more predictors are missing.
<code>method</code>	one of "anova", "poisson", "class" or "exp". If <code>method</code> is missing then the routine tries to make an intelligent guess. If <code>y</code> is a survival object, then <code>method="exp"</code> is assumed, if <code>y</code> has 2 columns then <code>method="poisson"</code> is assumed, if <code>y</code> is a factor then <code>method="class"</code> is assumed, otherwise <code>method="anova"</code> is assumed. It is wisest to specify the method directly, especially as more criteria are added to the function.  Alternatively, <code>method</code> can be a list of functions named <code>init</code> , <code>split</code> and <code>eval</code> . Examples are given in the file 'tests/usersplits.R' in the sources.
<code>model</code>	if logical: keep a copy of the model frame in the result? If the input value for <code>model</code> is a model frame (likely from an earlier call to the <code>rpart</code> function), then this frame is used rather than constructing new data.
<code>x</code>	keep a copy of the <code>x</code> matrix in the result.
<code>y</code>	keep a copy of the dependent variable in the result. If missing and <code>model</code> is supplied this defaults to <code>FALSE</code> .
<code>parms</code>	optional parameters for the splitting function. Anova splitting has no parameters. Poisson splitting has a single parameter, the coefficient of variation of the prior distribution on the rates. The default value is 1. Exponential splitting has the same parameter as Poisson. For classification splitting, the list can contain any of: the vector of prior probabilities (component <code>prior</code> ), the loss matrix (component <code>loss</code> ) or the splitting index (component <code>split</code> ). The priors must be positive and sum to 1. The loss matrix must have zeros on the diagonal and positive off-diagonal elements. The splitting index can be <code>gini</code> or <code>information</code> . The default priors are proportional to the data counts, the losses default to 1, and the split defaults to <code>gini</code> .
<code>control</code>	options that control details of the <code>rpart</code> algorithm.
<code>cost</code>	a vector of non-negative costs, one for each variable in the model. Defaults to one for all variables. These are scalings to be applied when considering splits, so the improvement on splitting on a variable is divided by its cost in deciding which split to choose.
<code>...</code>	arguments to <code>rpart.control</code> may also be specified in the call to <code>rpart</code> . They are checked against the list of valid arguments.

### Details

This differs from the `tree` function mainly in its handling of surrogate variables. In most details it follows Breiman et. al. quite closely.

### Value

An object of class `rpart`, a superset of class `tree`.

### References

Breiman, Friedman, Olshen, and Stone. (1984) *Classification and Regression Trees*. Wadsworth.

### See Also

**Examples**

```
fit <- rpart(Kyphosis ~ Age + Number + Start, data=kyphosis)
fit2 <- rpart(Kyphosis ~ Age + Number + Start, data=kyphosis,
             parms=list(prior=c(.65,.35), split='information'))
fit3 <- rpart(Kyphosis ~ Age + Number + Start, data=kyphosis,
             control=rpart.control(cp=.05))
par(mfrow=c(1,2), xpd=NA) # otherwise on some devices the text is clipped
plot(fit)
text(fit, use.n=TRUE)
plot(fit2)
text(fit2, use.n=TRUE)
```

---

rpart.control                      *Control for Rpart Models*

---

**Description**

Various parameters that control aspects of the rpart fit.

**Usage**

```
rpart.control(minsplit=20, minbucket=round(minsplit/3), cp=0.01,
             maxcompete=4, maxsurrogate=5, usesurrogate=2, xval=10,
             surrogatestyle=0, maxdepth=30, ...)
```

**Arguments**

minsplit	the minimum number of observations that must exist in a node, in order for a split to be attempted.
minbucket	the minimum number of observations in any terminal <code>&lt;leaf&gt;</code> node. If only one of <code>minbucket</code> or <code>minsplit</code> is specified, the code either sets <code>minsplit</code> to <code>minbucket*3</code> or <code>minbucket</code> to <code>minsplit/3</code> , as appropriate.
cp	complexity parameter. Any split that does not decrease the overall lack of fit by a factor of <code>cp</code> is not attempted. For instance, with <code>anova</code> splitting, this means that the overall <code>Rsquare</code> must increase by <code>cp</code> at each step. The main role of this parameter is to save computing time by pruning off splits that are obviously not worthwhile. Essentially, the user informs the program that any split which does not improve the fit by <code>cp</code> will likely be pruned off by cross-validation, and that hence the program need not pursue it.
maxcompete	the number of competitor splits retained in the output. It is useful to know not just which split was chosen, but which variable came in second, third, etc.
maxsurrogate	the number of surrogate splits retained in the output. If this is set to zero the compute time will be shortened, since approximately half of the computational time (other than setup) is used in the search for surrogate splits.
usesurrogate	how to use surrogates in the splitting process. 0= display only; an observation with a missing value for the primary split rule is not sent further down the tree. 1= use surrogates, in order, to split subjects missing the primary variable; if all surrogates are missing the observation is not split. 2= if all surrogates are missing, then send the observation in the majority direction. A value of 0 corresponds to the action of <code>tree</code> , and 2 to the recommendations of Breiman, et.al.

xval	number of cross-validations
surrogatestyle	controls the selection of a best surrogate. If set to 0 (default) the program uses the total number of correct classification for a potential surrogate variable, if set to 1 it uses the percent correct, calculated over the non-missing values of the surrogate. The first option more severely penalizes covariates with a large number of missing values.
maxdepth	Set the maximum depth of any node of the final tree, with the root node counted as depth 0 (past 30 rpart will give nonsense results on 32-bit machines).
...	mop up other arguments.

**Value**

A list containing the options.

**See Also**

[rpart](#)

---

rpart.object

*Recursive Partitioning and Regression Trees Object*

---

**Description**

These are objects representing fitted rpart trees.

**Value**

frame	data frame with one row for each node in the tree. The row.names of frame contain the (unique) node numbers that follow a binary ordering indexed by node depth. Elements of frame include var, a factor giving the variable used in the split at each node (leaf nodes are denoted by the string <leaf>), n, the size of each node, wt, the sum of case weights for the node, dev, the deviance of each node, yval, the fitted value of the response at each node, and splits, a two column matrix of left and right split labels for each node. All of these are the same as for an rpart object. Extra response information is in yval2, which contains the number of events at the node (poisson), or a matrix containing the fitted class, the class counts for each node and the class probabilities (classification). Also included in the frame are complexity, the complexity parameter at which this split will collapse, ncompete, the number of competitor splits retained, and nsurrogate, the number of surrogate splits retained.
where	integer vector, the same length as the number of observations in the root node, containing the row number of frame corresponding to the leaf node that each observation falls into.
splits	a numeric matrix describing the splits. The row label is the name of the split variable, and columns are count, the number of observations sent left or right by the split (for competitor splits this is the number that would have been sent left or right had this split been used, for surrogate splits it is the number missing the primary split variable which were decided using this surrogate), ncat, the

	number of categories or levels for the variable (+/-1 for a continuous variable), <code>improve</code> , which is the improvement in deviance given by this split, or, for surrogates, the concordance of the surrogate with the primary, and <code>split</code> , the numeric split point. The last column <code>adj</code> gives the adjusted concordance for surrogate splits. For a factor, the <code>split</code> column contains the row number of the <code>csplit</code> matrix. For a continuous variable, the sign of <code>ncat</code> determines whether the subset <code>x &lt; cutpoint</code> or <code>x &gt; cutpoint</code> is sent to the left.
<code>csplit</code>	this will be present only if one of the split variables is a factor. There is one row for each such split, and column <code>i = 1</code> if this level of the factor goes to the left, 3 if it goes to the right, and 2 if that level is not present at this node of the tree. For an ordered categorical variable all levels are marked as R/L, including levels that are not present.
<code>method</code>	the method used to grow the tree.
<code>cptable</code>	the table of optimal prunings based on a complexity parameter.
<code>terms</code>	an object of mode <code>expression</code> and class <code>term</code> summarizing the formula. Used by various methods, but typically not of direct relevance to users.
<code>call</code>	an image of the call that produced the object, but with the arguments all named and with the actual formula included as the formula argument. To re-evaluate the call, say <code>update(tree)</code> . Optional components include the matrix of predictors ( <code>x</code> ) and the response variable ( <code>y</code> ) used to construct the <code>rpart</code> object.

### Structure

The following components must be included in a legitimate `rpart` object. Of these, only the `where` component has the same length as the data used to fit the `rpart` object.

### See Also

[rpart](#).

---

`rpconvert`

*Update an rpart object*

---

### Description

`Rpart` objects changed (slightly) in their internal format in order to accommodate the changes for user-written split functions. This routine updates an old object to the new format.

### Usage

```
rpconvert(x)
```

### Arguments

`x` an `rpart` object

### Value

An updated object

**See Also**

rpart

---

rsq.rpart

*Plots the Approximate R-Square for the Different Splits*

---

**Description**

Produces 2 plots. The first plots the r-square (apparent and apparent - from cross-validation) versus the number of splits. The second plots the Relative Error(cross-validation) +/- 1-SE from cross-validation versus the number of splits.

**Usage**

```
rsq.rpart(x)
```

**Arguments**

`x` fitted model object of class `rpart`. This is assumed to be the result of some function that produces an object with the same named components as that returned by the `rpart` function.

**Side Effects**

Two plots are produced.

**Note**

The labels are only appropriate for the "anova" method.

**Examples**

```
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
rsq.rpart(z.auto)
```

---

snip.rpart

*Snip Subtrees of an Rpart Object*

---

**Description**

Creates a "snipped" `rpart` object, containing the nodes that remain after selected subtrees have been snipped off. The user can snip nodes using the `toss` argument, or interactively by clicking the mouse button on specified nodes within the graphics window.

**Usage**

```
snip.rpart(x, toss)
```

**Arguments**

x	fitted model object of class <code>rpart</code> . This is assumed to be the result of some function that produces an object with the same named components as that returned by the <code>rpart</code> function.
toss	an integer vector containing indices (node numbers) of all subtrees to be snipped off. If missing, user selects branches to snip off as described below.

**Details**

A dendrogram of `rpart` is expected to be visible on the graphics device, and a graphics input device (e.g., a mouse) is required. Clicking (the selection button) on a node displays the node number, sample size, response *y*-value, and Error (dev). Clicking a second time on the same node snips that subtree off and visually erases the subtree. This process may be repeated an number of times. Warnings result from selecting the root or leaf nodes. Clicking the exit button will stop the snipping process and return the resulting `rpart` object.

See the documentation for the specific graphics device for details on graphical input techniques.

**Value**

A `rpart` object containing the nodes that remain after specified or selected subtrees have been snipped off.

**Warning**

Visually erasing the plot is done by over-plotting with the background colour. This will do nothing if the background is transparent (often true for screen devices).

**See Also**

[plot.rpart](#)

**Examples**

```
## dataset not in R
## Not run:
z.survey <- rpart(market.survey) #grow the rpart object
plot(z.survey) #plot the tree
z.survey2 <- snip.rpart(z.survey,toss=2) #trim subtree at node 2
plot(z.survey2) #plot new tree

# can also interactively select the node using the mouse in the
# graphics window

## End(Not run)
```

---

solder

*Soldering of Components on Printed-Circuit Boards*

---

### Description

The `solder` data frame has 720 rows and 6 columns, representing a balanced subset of a designed experiment varying 5 factors on the soldering of components on printed-circuit boards.

### Usage

```
solder
```

### Format

This data frame contains the following columns:

`Opening` a factor with levels `L M S` indicating the amount of clearance around the mounting pad.

`Solder` a factor with levels `Thick Thin` giving the thickness of the solder used.

`Mask` a factor with levels `A1 .5 A3 B3 B6` indicating the type and thickness of mask used.

`PadType` a factor with levels `D4 D6 D7 L4 L6 L7 L8 L9 W4 W9` giving the size and geometry of the mounting pad.

`Panel` `1:3` indicating the panel on a board being tested.

`skips` a numeric vector giving the number of visible solder skips.

### Source

John M. Chambers and Trevor J. Hastie eds. (1992) *Statistical Models in S*, Wadsworth and Brooks/Cole, Pacific Grove, CA 1992.

### Examples

```
fit <- rpart(skips ~ Opening + Solder + Mask + PadType + Panel,
            data=solder, method='anova')
summary(residuals(fit))
plot(predict(fit), residuals(fit))
```

---

summary.rpart

*Summarize a Fitted Rpart Object*

---

### Description

Returns a detailed listing of a fitted `rpart` object.

### Usage

```
## S3 method for class 'rpart':
summary(object, cp=0, digits=getOption("digits"), file, ...)
```

**Arguments**

object	fitted model object of class <code>rpart</code> . This is assumed to be the result of some function that produces an object with the same named components as that returned by the <code>rpart</code> function.
digits	Number of significant digits to be used in the result.
cp	trim nodes with a complexity of less than <code>cp</code> from the listing.
file	write the output to a given file name. (Full listings of a tree are often quite long).
...	arguments to be passed to or from other methods.

**Details**

This function is a method for the generic function `summary` for class `"rpart"`. It can be invoked by calling `summary` for an object of the appropriate class, or directly by calling `summary.rpart` regardless of the class of the object.

**See Also**

`summary`, `rpart.object`, `printcp`.

**Examples**

```
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
summary(z.auto)
```

---

text.rpart

*Place Text on a Dendrogram*

---

**Description**

Labels the current plot of the tree dendrogram with text.

**Usage**

```
## S3 method for class 'rpart':
text(x, splits=TRUE, label, FUN=text, all=FALSE,
     pretty=NULL, digits=getOption("digits") - 3, use.n=FALSE,
     fancy=FALSE, fwidth=0.8, fheight=0.8, ...)
```

**Arguments**

x	fitted model object of class <code>rpart</code> . This is assumed to be the result of some function that produces an object with the same named components as that returned by the <code>rpart</code> function.
splits	logical flag. If <code>TRUE</code> (default), then the splits in the tree are labeled with the criterion for the split.
label	For compatibility with <code>rpart2</code> , ignored in this version (with a warning).
FUN	the name of a labeling function, e.g. <code>text</code> .
all	Logical. If <code>TRUE</code> , all nodes are labeled, otherwise just terminal nodes.

<code>pretty</code>	an integer denoting the extent to which factor levels in split labels will be abbreviated. A value of (0) signifies no abbreviation. A <code>NULL</code> , the default, signifies using elements of letters to represent the different factor levels.
<code>digits</code>	number of significant digits to include in numerical labels.
<code>use.n</code>	Logical. If <code>TRUE</code> , adds to label ( <code>\#events level1/\#events level2/etc.</code> for <code>class</code> , <code>n</code> for <code>anova</code> , and <code>\#events/n</code> for <code>poisson</code> and <code>exp</code> ).
<code>fancy</code>	Logical. If <code>TRUE</code> , nodes are represented by ellipses (interior nodes) and rectangles (leaves) and labeled by <code>yval</code> . The edges connecting the nodes are labeled by left and right splits.
<code>fwidth</code>	Relates to option <code>fancy</code> and the width of the ellipses and rectangles. If <code>fwidth &lt; 1</code> then it is a scaling factor (default = 0.8). If <code>fwidth &gt; 1</code> then it represents the number of character widths (for current graphical device) to use.
<code>fheight</code>	Relates to option <code>fancy</code> and the height of the ellipses and rectangles. If <code>fheight &lt; 1</code> then it is a scaling factor (default = 0.8). If <code>fheight &gt; 1</code> then it represents the number of character heights (for current graphical device) to use.
<code>...</code>	Graphical parameters may also be supplied as arguments to this function (see <code>par</code> ). As labels often extend outside the plot region it can be helpful to specify <code>xpd = TRUE</code> .

### Side Effects

the current plot of a tree dendrogram is labeled.

### See Also

[text](#), [plot.rpart](#), [rpart](#), [post.rpart](#), [abbreviate](#)

### Examples

```
freen.tr <- rpart(y ~ ., freeny)
plot(freen.tr)
text(freen.tr, use.n=TRUE, all=TRUE)
```

---

xpred.rpart

*Return Cross-Validated Predictions*

---

### Description

Gives the predicted values for an `rpart` fit, under cross validation, for a set of complexity parameter values.

### Usage

```
xpred.rpart(fit, xval=10, cp)
```

**Arguments**

<code>fit</code>	a <code>rpart</code> object.
<code>xval</code>	number of cross-validation groups. This may also be an explicit list of integers that define the cross-validation groups.
<code>cp</code>	the desired list of complexity values. By default it is taken from the <code>cptable</code> component of the fit.

**Details**

Complexity penalties are actually ranges, not values. If the `cp` values found in the table were .36, .28, and .13, for instance, this means that the first row of the table holds for all complexity penalties in the range  $[\text{.36}, 1]$ , the second row for `cp` in the range  $[\text{.28}, \text{.36})$  and the third row for  $[\text{.13}, \text{.28})$ . By default, the geometric mean of each interval is used for cross validation.

**Value**

A matrix with one row for each observation and one column for each complexity value.

**See Also**

[rpart](#)

**Examples**

```
fit <- rpart(Mileage ~ Weight, car.test.frame)
xmat <- xpred.rpart(fit)
xerr <- (xmat - car.test.frame$Mileage)^2
apply(xerr, 2, sum) # cross-validated error estimate

# approx same result as rel. error from printcp(fit)
apply(xerr, 2, sum)/var(car.test.frame$Mileage)
printcp(fit)
```

## Chapter 22

# The `spatial` package

---

`anova.trls`

*Anova tables for fitted trend surface objects*

---

### Description

Compute analysis of variance tables for one or more fitted trend surface model objects; where `anova.trls` is called with multiple objects, it passes on the arguments to `anovalist.trls`.

### Usage

```
## S3 method for class 'trls':  
anova(object, ...)  
anovalist.trls(object, ...)
```

### Arguments

<code>object</code>	A fitted trend surface model object from <code>surf.ls</code>
<code>...</code>	Further objects of the same kind

### Value

`anova.trls` and `anovalist.trls` return objects corresponding to their printed tabular output.

### References

```

---

correlogram                      *Compute Spatial Correlograms*

---

**Description**

Compute spatial correlograms of spatial data or residuals.

**Usage**

```
correlogram(krig, nint, plotit = TRUE, ...)
```

**Arguments**

krig	trend-surface or kriging object with columns <i>x</i> , <i>y</i> , and <i>z</i>
nint	number of bins used
plotit	logical for plotting
...	parameters for the plot

**Details**

Divides range of data into `nint` bins, and computes the covariance for pairs with separation in each bin, then divides by the variance. Returns results for bins with 6 or more pairs.

**Value**

*x* and *y* coordinates of the correlogram, and *cnt*, the number of pairs averaged per bin.

**Side Effects**

Plots the correlogram if `plotit = TRUE`.

```

---

expcov

*Spatial Covariance Functions*

---

**Description**

Spatial covariance functions for use with `surf.gls`.

**Usage**

```
expcov(r, d, alpha = 0, se = 1)
gaucov(r, d, alpha = 0, se = 1)
sphercov(r, d, alpha = 0, se = 1, D = 2)
```

**Arguments**

<code>r</code>	vector of distances at which to evaluate the covariance
<code>d</code>	range parameter
<code>alpha</code>	proportion of nugget effect
<code>se</code>	standard deviation at distance zero
<code>D</code>	dimension of spheres.

**Value**

vector of covariance values.

 Kaver

*Average K-functions from Simulations*

---

**Description**

Forms the average of a series of (usually simulated) K-functions.

**Usage**

```
Kaver(fs, nsim, ...)
```

**Arguments**

<code>fs</code>	full scale for K-fn
<code>nsim</code>	number of simulations
<code>...</code>	arguments to simulate one point process object

**Value**

list with components `x` and `y` of the average K-fn on L-scale.

Kfn

*Compute K-fn of a Point Pattern***Description**

Actually computes  $L = \sqrt{K/\pi}$ .

**Usage**

```
Kfn(pp, fs, k=100)
```

**Arguments**

pp	a list such as a pp object, including components <code>x</code> and <code>y</code>
fs	full scale of the plot
k	number of regularly spaced distances in (0, fs)

**Details**

relies on the domain `D` having been set by `ppinit` or `ppregion`.

**Value**

A list with components

<code>x</code>	vector of distances
<code>y</code>	vector of L-fn values
<code>k</code>	number of distances returned – may be less than <code>k</code> if <code>fs</code> is too large
<code>dmin</code>	minimum distance between pair of points
<code>lm</code>	maximum deviation from $L(t) = t$

---

`ppinit`*Read a Point Process Object from a File*

---

**Description**

Read a file in standard format and create a point process object.

**Usage**

```
ppinit(file)
```

**Arguments**

`file`                      string giving file name

**Details**

The file should contain  
the number of points  
a header (ignored)  
`xl xu yl yu scale`  
`x y` (repeated `n` times)

**Value**

class "pp" object with components `x, y, xl, xu, yl, yu`

**Side Effects**

Calls `ppregion` to set the domain.

pplik

*Pseudo-likelihood Estimation of a Strauss Spatial Point Process*

---

**Description**

Pseudo-likelihood estimation of a Strauss spatial point process.

**Usage**

```
pplik(pp, R, ng=50, trace=FALSE)
```

**Arguments**

<code>pp</code>	a <code>pp</code> object
<code>R</code>	the fixed parameter <code>R</code>
<code>ng</code>	use a <code>ng</code> x <code>ng</code> grid with border <code>R</code> in the domain for numerical integration.
<code>trace</code>	logical? Should function evaluations be printed?

**Value**

estimate for  $c$  in the interval  $[0, 1]$ .

pplik(pinetrees, 0.7)
```

---

`ppregion`*Set Domain for Spatial Point Pattern Analyses*

---

**Description**

Sets the rectangular domain  $(x_l, x_u) \times (y_l, y_u)$ .

**Usage**

```
ppregion(xl = 0, xu = 1, yl = 0, yu = 1)
```

**Arguments**

`xl` Either `xl` or a list containing components `xl`, `xu`, `yl`, `yu` (such as a point-process object)

`xu`

`yl`

`yu`

**Value**

none

**Side Effects**

initializes variables in the C subroutines.

---

`predict.trls`*Predict method for trend surface fits*

---

**Description**

Predicted values based on trend surface model object

**Usage**

```
## S3 method for class 'trls':  
predict(object, x, y, ...)
```

**Arguments**

<code>object</code>	Fitted trend surface model object returned by <code>surf.ls</code>
<code>x</code>	Vector of prediction location eastings (x coordinates)
<code>y</code>	Vector of prediction location northings (y coordinates)
<code>...</code>	further arguments passed to or from other methods.

**Value**

`predict.trls` produces a vector of predictions corresponding to the prediction locations. To display the output with `image` or `contour`, use `trmat` or convert the returned vector to matrix form.

**References**

z4 <- predict(topo4, x, y)
cat("2nd order predictions:", z2, "\n4th order predictions:", z4, "\n")
```

---

prmat

*Evaluate Kriging Surface over a Grid*

---

**Description**

Evaluate Kriging surface over a grid.

**Usage**

```
prmat(obj, xl, xu, yl, yu, n)
```

**Arguments**

<code>obj</code>	object returned by <code>surf.gls</code>
<code>xl</code>	limits of the rectangle for grid
<code>xu</code>	
<code>yl</code>	
<code>yu</code>	
<code>n</code>	use $n \times n$ grid within the rectangle

**Value**

list with components `x`, `y` and `z` suitable for `contour` and `image`.

Psim

*Simulate Binomial Spatial Point Process*

---

**Description**

Simulate Binomial spatial point process.

**Usage**

```
Psim(n)
```

**Arguments**

`n`                    number of points

**Details**

relies on the region being set by `ppinit` or `ppregion`.

**Value**

list of vectors of `x` and `y` coordinates.

**Side Effects**

uses the random number generator.

**References**

```

---

semat

*Evaluate Kriging Standard Error of Prediction over a Grid*

---

**Description**

Evaluate Kriging standard error of prediction over a grid.

**Usage**

```
semat(obj, xl, xu, yl, yu, n, se)
```

**Arguments**

obj	object returned by <code>surf.gls</code>
xl	limits of the rectangle for grid
xu	
yl	
yu	
n	use $n \times n$ grid within the rectangle
se	standard error at distance zero as a multiple of the supplied covariance. Otherwise estimated, and it assumed that a correlation function was supplied.

**Value**

list with components x, y and z suitable for `contour` and `image`.

**References**

```

---

SSI

*Simulates Sequential Spatial Inhibition Point Process*

---

**Description**

Simulates SSI (sequential spatial inhibition) point process.

**Usage**

```
SSI(n, r)
```

**Arguments**

n	number of points
r	inhibition distance

**Details**

uses the region set by `ppinit` or `ppregion`.

**Value**

list of vectors of  $x$  and  $y$  coordinates

**Side Effects**

uses the random number generator.

**Warnings**

will never return if  $r$  is too large and it cannot place  $n$  points.

**References**

```

Strauss

*Simulates Strauss Spatial Point Process***Description**

Simulates Strauss spatial point process.

**Usage**

```
Strauss(n, c=0, r)
```

**Arguments**

n	number of points
c	parameter $c$ in $[0, 1]$ . $c = 0$ corresponds to complete inhibition at distances up to $r$ .
r	inhibition distance

**Details**

Uses spatial birth-and-death process for  $4n$  steps, or for  $40n$  steps starting from a binomial pattern on the first call from an other function. Uses the region set by `ppinit` or `ppregion`.

**Value**

list of vectors of  $x$  and  $y$  coordinates

**Side Effects**

uses the random number generator

**References**

surf.gls

*Fits a Trend Surface by Generalized Least-squares***Description**

Fits a trend surface by generalized least-squares.

**Usage**

```
surf.gls(np, covmod, x, y, z, nx = 1000, ...)
```

**Arguments**

np	degree of polynomial surface
covmod	function to evaluate covariance or correlation function
x	x coordinates or a data frame with columns x, y, z
y	y coordinates
z	z coordinates. Will supersede x\$z
nx	Number of bins for table of the covariance. Increasing adds accuracy, and increases size of the object.
...	parameters for covmod

**Value**

list with components

beta	the coefficients
x	
y	
z	and others for internal use only.

**References**

trls.influence      *Regression diagnostics for trend surfaces*

---

**Description**

This function provides the basic quantities which are used in forming a variety of diagnostics for checking the quality of regression fits for trend surfaces calculated by `surf.ls`.

**Usage**

```

trls.influence(object)
## S3 method for class 'trls':
plot(x, border = "red", col = NA, pch = 4, cex = 0.6,
     add = FALSE, div = 8, ...)

```

**Arguments**

<code>object, x</code>	Fitted trend surface model from <code>surf.ls</code>
<code>div</code>	scaling factor for influence circle radii in <code>plot.trls</code>
<code>add</code>	add influence plot to existing graphics if TRUE
<code>border, col, pch, cex, ...</code>	additional graphical parameters

**Value**

`trls.influence` returns a list with components:

<code>r</code>	raw residuals as given by <code>residuals.trls</code>
<code>hii</code>	diagonal elements of the Hat matrix
<code>stresid</code>	standardised residuals
<code>Di</code>	Cook's statistic

---

variogram

*Compute Spatial Variogram*

---

**Description**

Compute spatial (semi-)variogram of spatial data or residuals.

**Usage**

```
variogram(krig, nint, plotit = TRUE, ...)
```

**Arguments**

krig	trend-surface or kriging object with columns <i>x</i> , <i>y</i> , and <i>z</i>
nint	number of bins used
plotit	logical for plotting
...	parameters for the plot

**Details**

Divides range of data into *nint* bins, and computes the average squared difference for pairs with separation in each bin. Returns results for bins with 6 or more pairs.

**Value**

*x* and *y* coordinates of the variogram and *cnt*, the number of pairs averaged per bin.

**Side Effects**

Plots the variogram if *plotit* = TRUE

## Chapter 23

# The `splines` package

---

`splines`-package      *Regression Spline Functions and Classes*

---

### Description

Regression spline functions and classes.

### Details

This package provides functions for working with regression splines using the B-spline basis, `bs`, and the natural cubic spline basis, `ns`.

For a complete list of functions, use `library(help="splines")`.

### Author(s)

Douglas M. Bates <bates@stat.wisc.edu>      and      William N. Venables  
<Bill.Venables@csiro.au>

Maintainer: R Core Team <R-core@r-project.org>

---

`asVector`      *Coerce an Object to a Vector*

---

### Description

This is a generic function. Methods for this function coerce objects of given classes to vectors.

### Usage

```
asVector(object)
```

### Arguments

`object`      An object.

**Details**

Methods for vector coercion in new classes must be created for the `asVector` generic instead of `as.vector`. The `as.vector` function is internal and not easily extended. Currently the only class with an `asVector` method is the `xyVector` class.

**Value**

a vector

**Author(s)**

Douglas Bates and Bill Venables

**See Also**

[xyVector](#)

**Examples**

```
require(stats)
ispl <- interpSpline( weight ~ height, women )
pred <- predict(ispl)
class(pred)
utils::str(pred)
asVector(pred)
```

---

backSpline

*Monotone Inverse Spline*

---

**Description**

Create a monotone inverse of a monotone natural spline.

**Usage**

```
backSpline(object)
```

**Arguments**

`object` an object that inherits from class `nbSpline` or `npolySpline`. That is, the object must represent a natural interpolation spline but it can be either in the B-spline representation or the piecewise polynomial one. The spline is checked to see if it represents a monotone function.

**Value**

An object of class `polySpline` that contains the piecewise polynomial representation of a function that has the appropriate values and derivatives at the knot positions to be an inverse of the spline represented by `object`. Technically this object is not a spline because the second derivative is not constrained to be continuous at the knot positions. However, it is often a much better approximation to the inverse than fitting an interpolation spline to the  $y/x$  pairs.

**Author(s)**

Douglas Bates and Bill Venables

**See Also**[interpSpline](#)**Examples**

```
require(graphics)
ispl <- interpSpline( women$height, women$weight )
bspl <- backSpline( ispl )
plot( bspl ) # plots over the range of the knots
points( women$weight, women$height )
```

bs

*B-Spline Basis for Polynomial Splines***Description**

Generate the B-spline basis matrix for a polynomial spline.

**Usage**

```
bs(x, df = NULL, knots = NULL, degree = 3, intercept = FALSE,
   Boundary.knots = range(x))
```

**Arguments**

<code>x</code>	the predictor variable. Missing values are allowed.
<code>df</code>	degrees of freedom; one can specify <code>df</code> rather than <code>knots</code> ; <code>bs()</code> then chooses <code>df-degree</code> (minus one if there is an intercept) knots at suitable quantiles of <code>x</code> (which will ignore missing values).
<code>knots</code>	the <i>internal</i> breakpoints that define the spline. The default is <code>NULL</code> , which results in a basis for ordinary polynomial regression. Typical values are the mean or median for one knot, quantiles for more knots. See also <code>Boundary.knots</code> .
<code>degree</code>	degree of the piecewise polynomial—default is 3 for cubic splines.
<code>intercept</code>	if <code>TRUE</code> , an intercept is included in the basis; default is <code>FALSE</code> .
<code>Boundary.knots</code>	boundary points at which to anchor the B-spline basis (default the range of the data). If both <code>knots</code> and <code>Boundary.knots</code> are supplied, the basis parameters do not depend on <code>x</code> . Data can extend beyond <code>Boundary.knots</code> .

**Value**

A matrix of dimension  $c(\text{length}(x), \text{df})$ , where either `df` was supplied or if `knots` were supplied,  $\text{df} = \text{length}(\text{knots}) + \text{degree} + 1$  if there is an intercept. Attributes are returned that correspond to the arguments to `bs`, and explicitly give the `knots`, `Boundary.knots` etc for use by `predict.bs()`.

`bs()` is based on the function `spline.des()`. It generates a basis matrix for representing the family of piecewise polynomials with the specified interior knots and degree, evaluated at the values of `x`. A primary use is in modeling formulas to directly specify a piecewise polynomial term in a model.

**See Also**

[ns](#), [poly](#), [smooth.spline](#), [predict.bs](#), [SafePrediction](#)

**Examples**

```
require(stats); require(graphics)
bs(women$height, df = 5)
summary(fml <- lm(weight ~ bs(height, df = 5), data = women))

## example of safe prediction
plot(women, xlab = "Height (in)", ylab = "Weight (lb)")
ht <- seq(57, 73, length.out = 200)
lines(ht, predict(fml, data.frame(height=ht)))
## Not run:
## Consistency:
x <- c(1:3, 5:6)
stopifnot(identical(bs(x), bs(x, df = 3)),
           !is.null(kk <- attr(bs(x), "knots")), # not true till 1.5.1
           length(kk) == 0)

## End(Not run)
```

---

 interpSpline

*Create an Interpolation Spline*

---

**Description**

Create an interpolation spline, either from `x` and `y` vectors, or from a formula/data.frame combination.

**Usage**

```
interpSpline(obj1, obj2, bSpline = FALSE, period = NULL,
             na.action = na.fail)
```

**Arguments**

<code>obj1</code>	Either a numeric vector of <code>x</code> values or a formula.
<code>obj2</code>	If <code>obj1</code> is numeric this should be a numeric vector of the same length. If <code>obj1</code> is a formula this can be an optional data frame in which to evaluate the names in the formula.
<code>bSpline</code>	If <code>TRUE</code> the b-spline representation is returned, otherwise the piecewise polynomial representation is returned. Defaults to <code>FALSE</code> .
<code>period</code>	An optional positive numeric value giving a period for a periodic interpolation spline.
<code>na.action</code>	a optional function which indicates what should happen when the data contain NAs. The default action ( <code>na.omit</code> ) is to omit any incomplete observations. The alternative action <code>na.fail</code> causes <code>interpSpline</code> to print an error message and terminate if there are any incomplete observations.

**Value**

An object that inherits from class `spline`. The object can be in the B-spline representation, in which case it will be of class `nbSpline` for natural B-spline, or in the piecewise polynomial representation, in which case it will be of class `npolySpline`.

**Author(s)**

Douglas Bates and Bill Venables

**See Also**

[splineKnots](#), [splineOrder](#), [periodicSpline](#).

**Examples**

```
require(graphics); require(stats)
ispl <- interpSpline( women$height, women$weight )
ispl2 <- interpSpline( weight ~ height, women )
# ispl and ispl2 should be the same
plot( predict( ispl, seq( 55, 75, length.out = 51 ) ), type = "l" )
points( women$height, women$weight )
plot( ispl ) # plots over the range of the knots
points( women$height, women$weight )
splineKnots( ispl )
```

---

 ns

*Generate a Basis Matrix for Natural Cubic Splines*

---

**Description**

Generate the B-spline basis matrix for a natural cubic spline.

**Usage**

```
ns(x, df = NULL, knots = NULL, intercept = FALSE,
   Boundary.knots = range(x))
```

**Arguments**

<code>x</code>	the predictor variable. Missing values are allowed.
<code>df</code>	degrees of freedom. One can supply <code>df</code> rather than <code>knots</code> ; <code>ns()</code> then chooses <code>df - 1 - intercept</code> knots at suitably chosen quantiles of <code>x</code> (which will ignore missing values).
<code>knots</code>	breakpoints that define the spline. The default is no knots; together with the natural boundary conditions this results in a basis for linear regression on <code>x</code> . Typical values are the mean or median for one knot, quantiles for more knots. See also <code>Boundary.knots</code> .
<code>intercept</code>	if <code>TRUE</code> , an intercept is included in the basis; default is <code>FALSE</code> .
<code>Boundary.knots</code>	boundary points at which to impose the natural boundary conditions and anchor the B-spline basis (default the range of the data). If both <code>knots</code> and <code>Boundary.knots</code> are supplied, the basis parameters do not depend on <code>x</code> . Data can extend beyond <code>Boundary.knots</code>

**Value**

A matrix of dimension `length(x) * df` where either `df` was supplied or if `knots` were supplied, `df = length(knots) + 1 + intercept`. Attributes are returned that correspond to the arguments to `ns`, and explicitly give the `knots`, `Boundary.knots` etc for use by `predict.ns()`.

`ns()` is based on the function `spline.des`. It generates a basis matrix for representing the family of piecewise-cubic splines with the specified sequence of interior knots, and the natural boundary conditions. These enforce the constraint that the function is linear beyond the boundary knots, which can either be supplied, else default to the extremes of the data. A primary use is in modeling formula to directly specify a natural spline term in a model.

```
require(stats); require(graphics)
ns(women$height, df = 5)
summary(fm1 <- lm(weight ~ ns(height, df = 5), data = women))

## example of safe prediction
plot(women, xlab = "Height (in)", ylab = "Weight (lb)")
ht <- seq(57, 73, length.out = 200)
lines(ht, predict(fm1, data.frame(height=ht)))
```

---

periodicSpline      *Create a Periodic Interpolation Spline*

---

### Description

Create a periodic interpolation spline, either from  $x$  and  $y$  vectors, or from a formula/data.frame combination.

### Usage

```
periodicSpline(obj1, obj2, knots, period = 2*pi, ord = 4)
```

### Arguments

obj1	either a numeric vector of $x$ values or a formula.
obj2	if obj1 is numeric this should be a numeric vector of the same length. If obj1 is a formula this can be an optional data frame in which to evaluate the names in the formula.
knots	optional numeric vector of knot positions.
period	positive numeric value giving the period for the periodic spline. Defaults to $2 * \pi$ .
ord	integer giving the order of the spline, at least 2. Defaults to 4. See <a href="#">splineOrder</a> for a definition of the order of a spline.

### Value

An object that inherits from class `spline`. The object can be in the B-spline representation, in which case it will be a `pbSpline` object, or in the piecewise polynomial representation (a `ppolySpline` object).

### Author(s)

Douglas Bates and Bill Venables

### See Also

[splineKnots](#), [interpSpline](#)

### Examples

```
require(graphics); require(stats)
xx <- seq(-pi, pi, length.out = 16)[-1]
yy <- sin( xx )
frm <- data.frame( xx, yy )
( pisp1 <- periodicSpline( xx, yy, period = 2 * pi ) )
pisp2 <- periodicSpline( yy ~ xx, frm, period = 2 * pi )
stopifnot(all.equal(pisp1, pisp2))# pisp1 and pisp2 are the same

plot( pisp1 )                    # displays over one period
points( yy ~ xx, col = "brown" )
plot( predict( pisp1, seq(-3*pi, 3*pi, length.out = 101) ), type = "l" )
```

---

polySpline	<i>Piecewise Polynomial Spline Representation</i>
------------	---

---

### Description

Create the piecewise polynomial representation of a spline object.

### Usage

```
polySpline(object, ...)  
as.polySpline(object, ...)
```

### Arguments

object	An object that inherits from class <code>spline</code> .
...	Optional additional arguments. At present no additional arguments are used.

### Value

An object that inherits from class `polySpline`. This is the piecewise polynomial representation of a univariate spline function. It is defined by a set of distinct numeric values called knots. The spline function is a polynomial function between each successive pair of knots. At each interior knot the polynomial segments on each side are constrained to have the same value of the function and some of its derivatives.

### Author(s)

Douglas Bates and Bill Venables

### See Also

[interpSpline](#), [periodicSpline](#), [splineKnots](#), [splineOrder](#)

### Examples

```
require(graphics)  
ispl <- polySpline( interpSpline( weight ~ height, women, bSpline = TRUE ) )  
print( ispl ) # print the piecewise polynomial representation  
plot( ispl ) # plots over the range of the knots  
points( women$height, women$weight )
```

---

`predict.bs`*Evaluate a Spline Basis*

---

### Description

Evaluate a predefined spline basis at given values.

### Usage

```
## S3 method for class 'bs':  
predict(object, newx, ...)  
  
## S3 method for class 'ns':  
predict(object, newx, ...)
```

### Arguments

<code>object</code>	the result of a call to <code>bs</code> or <code>ns</code> having attributes describing knots, degree, etc.
<code>newx</code>	the <code>x</code> values at which evaluations are required.
<code>...</code>	Optional additional arguments. At present no additional arguments are used.

### Value

An object just like `object`, except evaluated at the new values of `x`.

These are methods for the generic function `predict` for objects inheriting from classes "bs" or "ns". See `predict` for the general behavior of this function.

### See Also

`bs`, `ns`, `poly`.

### Examples

```
require(stats)  
basis <- ns(women$height, df = 5)  
newX <- seq(58, 72, length.out = 51)  
# evaluate the basis at the new data  
predict(basis, newX)
```

---

predict.bSpline      *Evaluate a Spline at New Values of x*

---

### Description

The `predict` methods for the classes that inherit from the virtual classes `bSpline` and `polySpline` are used to evaluate the spline or its derivatives. The `plot` method for a spline object first evaluates `predict` with the `x` argument missing, then plots the resulting `xyVector` with `type = "l"`.

### Usage

```
## S3 method for class 'bSpline':
predict(object, x, nseg=50, deriv=0, ...)
## S3 method for class 'nbSpline':
predict(object, x, nseg=50, deriv=0, ...)
## S3 method for class 'pbSpline':
predict(object, x, nseg=50, deriv=0, ...)
## S3 method for class 'npolySpline':
predict(object, x, nseg=50, deriv=0, ...)
## S3 method for class 'ppolySpline':
predict(object, x, nseg=50, deriv=0, ...)
```

### Arguments

<code>object</code>	An object that inherits from the <code>bSpline</code> or the <code>polySpline</code> class.
<code>x</code>	A numeric vector of <code>x</code> values at which to evaluate the spline. If this argument is missing a suitable set of <code>x</code> values is generated as a sequence of <code>nseg</code> segments spanning the range of the knots.
<code>nseg</code>	A positive integer giving the number of segments in a set of equally-spaced <code>x</code> values spanning the range of the knots in <code>object</code> . This value is only used if <code>x</code> is missing.
<code>deriv</code>	An integer between 0 and <code>splineOrder(object) - 1</code> specifying the derivative to evaluate.
<code>...</code>	further arguments passed to or from other methods.

### Value

	an <code>xyVector</code> with components
<code>x</code>	the supplied or inferred numeric vector of <code>x</code> values
<code>y</code>	the value of the spline (or its <code>deriv</code> 'th derivative) at the <code>x</code> vector

### Author(s)

Douglas Bates and Bill Venables

### See Also

[xyVector](#), [interpSpline](#), [periodicSpline](#)

**Examples**

```
require(graphics); require(stats)
ispl <- interpSpline( weight ~ height, women )
opar <- par(mfrow = c(2, 2), las = 1)
plot(predict(ispl, nseg = 201),      # plots over the range of the knots
      main = "Original data with interpolating spline", type = "l",
      xlab = "height", ylab = "weight")
points(women$height, women$weight, col = 4)
plot(predict(ispl, nseg = 201, deriv = 1),
      main = "First derivative of interpolating spline", type = "l",
      xlab = "height", ylab = "weight")
plot(predict(ispl, nseg = 201, deriv = 2),
      main = "Second derivative of interpolating spline", type = "l",
      xlab = "height", ylab = "weight")
plot(predict(ispl, nseg = 401, deriv = 3),
      main = "Third derivative of interpolating spline", type = "l",
      xlab = "height", ylab = "weight")
par(opar)
```

splineDesign

*Design Matrix for B-splines***Description**

Evaluate the design matrix for the B-splines defined by `knots` at the values in `x`.

**Usage**

```
splineDesign(knots, x, ord = 4, derivs, outer.ok = FALSE)
spline.des(knots, x, ord = 4, derivs, outer.ok = FALSE)
```

**Arguments**

<code>knots</code>	a numeric vector of knot positions with non-decreasing values.
<code>x</code>	a numeric vector of values at which to evaluate the B-spline functions or derivatives. Unless <code>outer.ok</code> is true, the values in <code>x</code> must be between <code>knots[ord]</code> and <code>knots[ length(knots) + 1 - ord ]</code> .
<code>ord</code>	a positive integer giving the order of the spline function. This is the number of coefficients in each piecewise polynomial segment, thus a cubic spline has order 4. Defaults to 4.
<code>derivs</code>	an integer vector of the same length as <code>x</code> and with values between 0 and <code>ord - 1</code> . The derivative of the given order is evaluated at the <code>x</code> positions. Defaults to a vector of zeroes of the same length as <code>x</code> .
<code>outer.ok</code>	logical indicating if <code>x</code> should be allowed outside the <i>inner</i> knots, see the <code>x</code> argument.

**Value**

A matrix with `length( x )` rows and `length( knots ) - ord` columns. The *i*'th row of the matrix contains the coefficients of the B-splines (or the indicated derivative of the B-splines) defined by the `knot` vector and evaluated at the *i*'th value of `x`. Each B-spline is defined by a set of `ord` successive knots so the total number of B-splines is `length(knots) - ord`.

**Note**

The older `spline.des` function takes the same arguments but returns a list with several components including `knots`, `ord`, `derivs`, and `design`. The `design` component is the same as the value of the `splineDesign` function.

**Author(s)**

Douglas Bates and Bill Venables

**Examples**

```
require(graphics)
splineDesign(knots = 1:10, x = 4:7)

knots <- c(1,1.8,3:5,6.5,7,8.1,9.2,10)# 10 => 10-4 = 6 Basis splines
x <- seq(min(knots)-1, max(knots)+1, length.out=501)
bb <- splineDesign(knots, x=x, outer.ok = TRUE)

plot(range(x), c(0,1), type="n", xlab="x", ylab="",
      main= "B-splines - sum to 1 inside inner knots")
mtext(expression(B[j](x) * and "*" sum(B[j](x), j==1, 6)), adj=0)
abline(v=knots, lty=3, col="light gray")
abline(v=knots[c(4,length(knots)-3)], lty=3, col="gray10")
lines(x, rowSums(bb), col="gray", lwd=2)
matlines(x, bb, ylim = c(0,1), lty=1)
```

---

splineKnots

*Knot Vector from a Spline*

---

**Description**

Return the knot vector corresponding to a spline object.

**Usage**

```
splineKnots(object)
```

**Arguments**

`object`            an object that inherits from class "spline".

**Value**

A non-decreasing numeric vector of knot positions.

**Author(s)**

Douglas Bates and Bill Venables

**Examples**

```
ispl <- interpSpline( weight ~ height, women )
splineKnots( ispl )
```

---

splineOrder	<i>Determine the Order of a Spline</i>
-------------	--

---

**Description**

Return the order of a spline object.

**Usage**

```
splineOrder(object)
```

**Arguments**

object      An object that inherits from class "spline".

**Details**

The order of a spline is the number of coefficients in each piece of the piecewise polynomial representation. Thus a cubic spline has order 4.

**Value**

A positive integer.

**Author(s)**

Douglas Bates and Bill Venables

**See Also**

[splineKnots](#), [interpSpline](#), [periodicSpline](#)

**Examples**

```
splineOrder( interpSpline( weight ~ height, women ) )
```

---

xyVector	<i>Construct an xyVector Object</i>
----------	-------------------------------------

---

**Description**

Create an object to represent a set of x-y pairs. The resulting object can be treated as a matrix or as a data frame or as a vector. When treated as a vector it reduces to the `y` component only.

The result of functions such as `predict.spline` is returned as an `xyVector` object so the x-values used to generate the y-positions are retained, say for purposes of generating plots.

**Usage**

```
xyVector(x, y)
```

**Arguments**

*x* a numeric vector  
*y* a numeric vector of the same length as *x*

**Value**

An object of class `xyVector` with components

*x* a numeric vector  
*y* a numeric vector of the same length as *x*

**Author(s)**

Douglas Bates and Bill Venables

**Examples**

```
require(stats); require(graphics)
ispl <- interpSpline( weight ~ height, women )
weights <- predict( ispl, seq( 55, 75, length.out = 51 ) )
class( weights )
plot( weights, type = "l", xlab = "height", ylab = "weight" )
points( women$height, women$weight )
weights
```

# Chapter 24

## The `stats4` package

---

`stats4-package`      *Statistical Functions using S4 Classes*

---

### Description

Statistical Functions using S4 classes.

### Details

This package contains functions and classes for statistics using the [S version 4](#) class system.

The methods currently support maximum likelihood (function `mle()` returning class `"mle"`), including methods for [AIC](#) and [BIC](#) for model selection.

### Author(s)

R Development Core Team and contributors worldwide

Maintainer: R Core Team <[R-core@r-project.org](mailto:R-core@r-project.org)>

---

`AIC-methods`      *Methods for Function 'AIC' in Package 'stats4'*

---

### Description

Calculate the Akaike information criterion for a fitted model object.

### Methods

`signature(object = "ANY")` Generic function: see [AIC](#).

---

**BIC***Bayesian Information Criterion*

---

**Description**

This generic function calculates the Bayesian information criterion, also known as Schwarz's Bayesian criterion (SBC), for one or several fitted model objects for which a log-likelihood value can be obtained, according to the formula  $-2\log\text{-likelihood} + n_{par} \log(n_{obs})$ , where  $n_{par}$  represents the number of parameters and  $n_{obs}$  the number of observations in the fitted model.

**Usage**

```
BIC(object, ...)
```

**Arguments**

<code>object</code>	An object of a suitable class for the BIC to be calculated - usually a "logLik" object or an object for which a <code>logLik</code> method exists.
<code>...</code>	optionally more fitted model objects.

**Value**

If just one object is provided, returns a numeric value with the corresponding BIC; if multiple objects are provided, returns a `data.frame` with rows corresponding to the objects and columns representing the number of parameters in the model (`df`) and the BIC.

[logLik-methods](#), [AIC-methods](#)

**Examples**

```
lm1 <- lm(Fertility ~ . , data = swiss)
AIC(lm1)
BIC(lm1)

## with two models:
lm1.< <- update(lm1, . ~ . -Examination)
AIC(lm1, lm1.)
BIC(lm1, lm1.)
```

---

`coef-methods`*Methods for Function 'coef' in Package 'stats4'*

---

**Description**

Extract the coefficient vector from "mle" objects.

**Methods**

`signature(object = "ANY")` Generic function: see [coef](#).

`signature(object = "mle")` Extract the full coefficient vector (including any fixed coefficients) from the fit.

`signature(object = "summary.mle")` Extract the coefficient vector and standard errors from the summary of the fit.

---

`confint-methods`*Methods for Function 'confint' in Package 'stats4'*

---

**Description**

Generate confidence intervals

**Methods**

`signature(object = "ANY")` Generic function: see [confint](#).

`signature(object = "mle")` First generate profile and then confidence intervals from the profile.

`signature(object = "profile.mle")` Generate confidence intervals based on likelihood profile.

---

`logLik-methods`*Methods for Function 'logLik' in Package 'stats4'*

---

**Description**

Extract the maximized log-likelihood from "mle" objects.

**Methods**

`signature(object = "ANY")` Generic function: see [logLik](#).

`signature(object = "mle")` Extract log-likelihood from the fit.

mle

*Maximum Likelihood Estimation***Description**

Estimate parameters by the method of maximum likelihood.

**Usage**

```
mle(minuslogl, start = formals(minuslogl), method = "BFGS",
    fixed = list(), ...)
```

**Arguments**

minuslogl	Function to calculate negative log-likelihood.
start	Named list. Initial values for optimizer.
method	Optimization method to use. See <a href="#">optim</a> .
fixed	Named list. Parameter values to keep fixed during optimization.
...	Further arguments to pass to <a href="#">optim</a> .

**Details**

The [optim](#) optimizer is used to find the minimum of the negative log-likelihood. An approximate covariance matrix for the parameters is obtained by inverting the Hessian matrix at the optimum.

**Value**

An object of class [mle-class](#).

**Note**

Be careful to note that the argument is  $-\log L$  (not  $-2 \log L$ ). It is for the user to ensure that the likelihood is correct, and that asymptotic likelihood inference is valid.

**See Also**

[mle-class](#)

**Examples**

```
x <- 0:10
y <- c(26, 17, 13, 12, 20, 5, 9, 8, 5, 4, 8)
## This needs a constrained parameter space: most methods will accept NA
ll <- function(ymax=15, xhalf=6)
  if(ymax > 0 && xhalf > 0) -sum(stats::dpois(y, lambda=ymax/(1+x/xhalf), log=TRUE)) else
  (fit <- mle(ll))
mle(ll, fixed=list(xhalf=6))
## alternative using bounds on optimization
ll2 <- function(ymax=15, xhalf=6)
  -sum(stats::dpois(y, lambda=ymax/(1+x/xhalf), log=TRUE))
mle(ll2, method="L-BFGS-B", lower=rep(0, 2))
```

```

summary(fit)
logLik(fit)
vcov(fit)
plot(profile(fit), absVal=FALSE)
confint(fit)

## use bounded optimization
## the lower bounds are really > 0, but we use >=0 to stress-test profiling
(fit1 <- mle(l1, method="L-BFGS-B", lower=c(0, 0)))
plot(profile(fit1), absVal=FALSE)

## a better parametrization:
l12 <- function(lymax=log(15), lxhalf=log(6))
  -sum(stats::dpois(y, lambda=exp(lymax)/(1+x/exp(lxhalf)), log=TRUE))
(fit2 <- mle(l12))
plot(profile(fit2), absVal=FALSE)
exp(confint(fit2))

```

---

mle-class

*Class "mle" for Results of Maximum Likelihood Estimation*

---

## Description

This class encapsulates results of a generic maximum likelihood procedure.

## Objects from the Class

Objects can be created by calls of the form `new("mle", ...)`, but most often as the result of a call to `mle`.

## Slots

**call**: Object of class "language". The call to `mle`.  
**coef**: Object of class "numeric". Estimated parameters.  
**fullcoef**: Object of class "numeric". Fixed and estimated parameters.  
**vcov**: Object of class "matrix". Approximate variance-covariance matrix.  
**min**: Object of class "numeric". Minimum value of objective function.  
**details**: Object of class "list". List returned from `optim`.  
**minuslogl**: Object of class "function". The negative loglikelihood function.  
**method**: Object of class "character". The optimization method used.

## Methods

**confint** signature(object = "mle"): Confidence intervals from likelihood profiles.  
**logLik** signature(object = "mle"): Extract maximized log-likelihood.  
**profile** signature(fitted = "mle"): Likelihood profile generation.  
**show** signature(object = "mle"): Display object briefly.  
**summary** signature(object = "mle"): Generate object summary.  
**update** signature(object = "mle"): Update fit.  
**vcov** signature(object = "mle"): Extract variance-covariance matrix.

---

 plot-methods

*Methods for Function 'plot' in Package 'stats4'*

---

**Description**

Plot profile likelihoods for "mle" objects.

**Usage**

```
## S4 method for signature 'profile.mle,missing':
plot(x, levels, conf = c(99, 95, 90, 80, 50)/100, nseg = 50,
     absVal = TRUE, ...)
```

**Arguments**

x	an object of class "profile.mle"
levels	levels, on the scale of the absolute value of a t statistic, at which to interpolate intervals. Usually conf is used instead of giving levels explicitly.
conf	a numeric vector of confidence levels for profile-based confidence intervals on the parameters.
nseg	an integer value giving the number of segments to use in the spline interpolation of the profile t curves.
absVal	a logical value indicating whether or not the plots should be on the scale of the absolute value of the profile t. Defaults to TRUE.
...	other arguments to the plot function can be passed here.

**Methods**

signature(x = "ANY", y = "ANY") Generic function: see [plot](#).

signature(x = "profile.mle", y = "missing") Plot likelihood profiles for x.

---

 profile-methods

*Methods for Function profile in Package 'stats4'*

---

**Description**

Profile likelihood for "mle" objects.

**Usage**

```
## S4 method for signature 'mle':
profile(fitted, which = 1:p, maxsteps = 100, alpha = 0.01,
       zmax = sqrt(qchisq(1 - alpha, 1L)), del = zmax/5,
       trace = FALSE, ...)
```

**Arguments**

fitted	Object to be profiled
which	Optionally select subset of parameters to profile.
maxsteps	Maximum number of steps to bracket <code>zmax</code> .
alpha	Significance level corresponding to <code>zmax</code> , based on a Scheffe-style multiple testing interval. Ignored if <code>zmax</code> is specified.
zmax	Cutoff for the profiled value of the signed root-likelihood.
del	Initial stepsize on root-likelihood scale.
trace	Logical. Print intermediate results.
...	Currently unused.

**Details**

The profiling algorithm tries to find an approximately evenly spaced set of at least five parameter values (in each direction from the optimum) to cover the root-likelihood function. Some care is taken to try and get sensible results in cases of high parameter curvature. Notice that it may not always be possible to obtain the cutoff value, since the likelihood might level off.

**Value**

An object of class "profile.mle", see "profile.mle-class".

**Methods**

`signature(fitted = "ANY")` Generic function: see [profile](#).  
`signature(fitted = "mle")` Profile the likelihood in the vicinity of the optimum of an "mle" object.

---

profile.mle-class    *Class "profile.mle"; Profiling information for "mle" object*

---

**Description**

Likelihood profiles along each parameter of likelihood function

**Objects from the Class**

Objects can be created by calls of the form `new("profile.mle", ...)`, but most often by invoking `profile` on an "mle" object.

**Slots**

`profile`: Object of class "list". List of profiles, one for each requested parameter. Each profile is a data frame with the first column called `z` being the signed square root of the  $-2 \log$  likelihood ratio, and the others being the parameters with names prefixed by `par.vals`.

`summary`: Object of class "summary.mle". Summary of object being profiled.

**Methods**

**confint** `signature(object = "profile.mle")`: Use `profile` to generate approximate confidence intervals for parameters.

**plot** `signature(x = "profile.mle", y = "missing")`: Plot profiles for each parameter.

**See Also**

[mle](#), [mle-class](#), [summary.mle-class](#)

---

show-methods

*Methods for Function show in Package 'stats4'*

---

**Description**

Show objects of classes `mle` and `summary.mle`

**Methods**

`signature(object = "mle")` Print simple summary of `mle` object. Just the coefficients and the call.

`signature(object = "summary.mle")` Shows call, table of coefficients and standard errors, and  $-2 \log L$ .

---

summary-methods

*Methods for Function summary in Package 'stats4'*

---

**Description**

Summarize objects

**Methods**

`signature(object = "ANY")` Generic function

`signature(object = "mle")` Generate a summary as an object of class `"summary.mle"`, containing estimates, asymptotic SE, and value of  $-2 \log L$ .

---

summary.mle-class *Class "summary.mle", summary of "mle" objects*

---

### Description

Extract of "mle" object

### Objects from the Class

Objects can be created by calls of the form `new("summary.mle", ...)`, but most often by invoking `summary` on an "mle" object. They contain values meant for printing by `show`.

### Slots

**call:** Object of class "language" The call that generated the "mle" object.

**coef:** Object of class "matrix". Estimated coefficients and standard errors

**m2logL:** Object of class "numeric". Minus twice the log likelihood.

### Methods

**show** signature(object = "summary.mle"): Pretty-prints object

**coef** signature(object = "summary.mle"): Extracts the contents of the `coef` slot

### See Also

[summary](#), [mle](#), [mle-class](#)

---

update-methods *Methods for Function 'update' in Package 'stats4'*

---

### Description

Update "mle" objects.

### Usage

```
## S4 method for signature 'mle':
update(object, ..., evaluate = TRUE)
```

### Arguments

`object` An existing fit.

`...` Additional arguments to the call, or arguments with changed values. Use `name=NULL` to remove the argument `name`.

`evaluate` If true evaluate the new call else return the call.

**Methods**

signature(object = "ANY") Generic function: see [update](#).

signature(object = "mle") Update a fit.

**Examples**

```
x <- 0:10
y <- c(26, 17, 13, 12, 20, 5, 9, 8, 5, 4, 8)
ll <- function(ymax=15, xhalf=6)
  -sum(stats::dpois(y, lambda=ymax/(1+x/xhalf), log=TRUE))
fit <- mle(ll)
## note the recorded call contains ..1, a problem with S4 dispatch
update(fit, fixed=list(xhalf=3))
```

---

vcov-methods

*Methods for Function 'vcov' in Package 'stats4'*

---

**Description**

Extract the approximate variance-covariance matrix from "mle" objects.

**Methods**

signature(object = "ANY") Generic function: see [vcov](#).

signature(object = "mle") Extract the estimated variance-covariance matrix for the estimated parameters (if any).

## Chapter 25

# The survival package

---

aareg	<i>Aalen's additive regression model for censored data</i>
-------	--

---

### Description

Returns an object of class "aareg" that represents an Aalen model.

### Usage

```
aareg(formula, data, weights, subset, na.action,  
      qrtol=1e-07, nmin, dfbeta=FALSE, taper=1,  
      test = c('aalen', 'variance', 'nrisk'),  
      model=FALSE, x=FALSE, y=FALSE)
```

### Arguments

formula	a formula object, with the response on the left of a '~' operator and the terms, separated by + operators, on the right. The response must be a <code>Surv</code> object. Due to a particular computational approach that is used, the model <b>MUST</b> include an intercept term. If "-1" is used in the model formula the program will ignore it.
data	data frame in which to interpret the variables named in the <code>formula</code> , <code>subset</code> , and <code>weights</code> arguments. This may also be a single number to handle some special cases – see below for details. If <code>data</code> is missing, the variables in the model formula should be in the search path.
weights	vector of observation weights. If supplied, the fitting algorithm minimizes the sum of the weights multiplied by the squared residuals (see below for additional technical details). The length of <code>weights</code> must be the same as the number of observations. The weights must be nonnegative and it is recommended that they be strictly positive, since zero weights are ambiguous. To exclude particular observations from the model, use the <code>subset</code> argument instead of zero weights.
subset	expression specifying which subset of observations should be used in the fit. This can be a logical vector (which is replicated to have length equal to the number of observations), a numeric vector indicating the observation numbers to be included, or a character vector of the observation names that should be included. All observations are included by default.

<code>na.action</code>	a function to filter missing data. This is applied to the <code>model.frame</code> after any <code>subset</code> argument has been applied. The default is <code>na.fail</code> , which returns an error if any missing values are found. An alternative is <code>na.exclude</code> , which deletes observations that contain one or more missing values.
<code>qrtol</code>	tolerance for detection of singularity in the QR decomposition
<code>nmin</code>	minimum number of observations for an estimate; defaults to 3 times the number of covariates. This essentially truncates the computations near the tail of the data set, when <code>n</code> is small and the calculations can become numerically unstable.
<code>dfbeta</code>	should the array of <code>dfbeta</code> residuals be computed. This implies computation of the sandwich variance estimate. The residuals will always be computed if there is a <code>cluster</code> term in the model formula.
<code>taper</code>	allows for a smoothed variance estimate. $\text{Var}(x)$ , where <code>x</code> is the set of covariates, is an important component of the calculations for the Aalen regression model. At any given time point <code>t</code> , it is computed over all subjects who are still at risk at time <code>t</code> . The <code>taper</code> argument allows smoothing these estimates, for example <code>taper=(1:4)/4</code> would cause the variance estimate used at any event time to be a weighted average of the estimated variance matrices at the last 4 death times, with a weight of 1 for the current death time and decreasing to 1/4 for prior event times. The default value gives the standard Aalen model.
<code>test</code>	selects the weighting to be used, for computing an overall “average” coefficient vector over time and the subsequent test for equality to zero.
<code>model, x, y</code>	should copies of the model frame, the <code>x</code> matrix of predictors, or the response vector <code>y</code> be included in the saved result.

### Details

The Aalen model assumes that the cumulative hazard  $H(t)$  for a subject can be expressed as  $a(t) + X B(t)$ , where  $a(t)$  is a time-dependent intercept term,  $X$  is the vector of covariates for the subject (possibly time-dependent), and  $B(t)$  is a time-dependent matrix of coefficients. The estimates are inherently non-parametric; a fit of the model will normally be followed by one or more plots of the estimates.

The estimates may become unstable near the tail of a data set, since the increment to  $B$  at time `t` is based on the subjects still at risk at time `t`. The `tolerance` and/or `nmin` parameters may act to truncate the estimate before the last death. The `taper` argument can also be used to smooth out the tail of the curve. In practice, the addition of a taper such as 1:10 appears to have little effect on death times when `n` is still reasonably large, but can considerably dampen wild oscillations in the tail of the plot.

### Value

an object of class "aareg" representing the fit.

---

anova.coxph	<i>Analysis of Deviance for a Cox model.</i>
-------------	--

---

**Description**

Compute an analysis of deviance table for one or more Cox model fits.

**Usage**

```
## S3 method for class 'coxph':
anova(object, ..., test = 'Chisq')
```

**Arguments**

object	An object of class <code>coxph</code>
...	Further <code>coxph</code> objects
test	a character string. The appropriate test is a chisquare, all other choices result in no test being done.

**Details**

Specifying a single object gives a sequential analysis of deviance table for that fit. That is, the reductions in the model log-likelihood as each term of the formula is added in turn are given in as the rows of a table, plus the log-likelihoods themselves. A robust variance estimate is normally used in situations where the model may be mis-specified, e.g., multiple events per subject. In this case a comparison of partial-likelihood values does not make sense, and `anova` will refuse to print results.

If more than one object is specified, the table has a row for the degrees of freedom and loglikelihood for each model. For all but the first model, the change in degrees of freedom and loglik is also given. (This only make statistical sense if the models are nested.) It is conventional to list the models from smallest to largest, but this is up to the user.

The table will optionally contain test statistics (and P values) comparing the reduction in loglik for each row.

**Value**

An object of class "anova" inheriting from class "data.frame".

**Warning**

The comparison between two or more models by `anova` or will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values.

**See Also**

[coxph](#), [anova](#).

**Examples**

```
fit <- coxph(Surv(futime, fustat) ~ resid.ds *rx + ecog.ps, data = ovarian)
anova(fit)
fit2 <- coxph(Surv(futime, fustat) ~ resid.ds +rx + ecog.ps, data=ovarian)
anova(fit2, fit)
```

---

attrassign

---

*Create new-style "assign" attribute*

---

**Description**

The "assign" attribute on model matrices describes which columns come from which terms in the model formula. It has two versions. R uses the original version, but the alternate version found in S-plus is sometimes useful.

**Usage**

```
## Default S3 method:
attrassign(object, tt, ...)
## S3 method for class 'lm':
attrassign(object, ...)
```

**Arguments**

object	model matrix or linear model object
tt	terms object
...	ignored

**Details**

For instance consider the following

```
survreg(Surv(time, status) ~ age + sex + factor(ph.ecog), lung)
```

R gives the compact for for assign, a vector (0, 1, 2, 3, 3, 3); which can be read as “the first column of the X matrix (intercept) goes with none of the terms, the second column of X goes with term 1 of the model equation, the third column of X with term 2, and columns 4-6 with term 3”.

The alternate (S-Plus default) form is a list

```
$(Intercept)      1
$age              2
$sex              3
$factor(ph.ecog) 4 5 6
```

### Value

A list with names corresponding to the term names and elements that are vectors indicating which columns come from which terms

### See Also

[terms,model.matrix](#)

### Examples

```
formula <- Surv(time,status)~factor(edema)
tt <- terms(formula)
mf <- model.frame(tt,data=pbcc)
mm <- model.matrix(tt,mf)
## a few rows of data
mm[1:3,]
## old-style assign attribute
attr(mm,"assign")
## alternate style assign attribute
attrassign(mm,tt)
```

---

basehaz

*Compute the baseline survival curve for a Cox model*

---

### Description

Compute the baseline survival curve for a Cox model.

### Usage

```
basehaz(fit, centered = TRUE)
```

### Arguments

fit	The result of a <code>coxph</code> fit.
centered	If TRUE, the resultant curve is for a hypothetical subject whose covariate values are the corresponding means from the original data, otherwise for a hypothetical subject with a mean vector of zero.

## Details

This function exists primarily because users will look for the phrase 'baseline hazard' (often SAS converts looking for familiar keywords.) The primary function for creating a survival curve is `survfit`, which this calls. See that manual page for more options, including confidence limits and the ability to use other covariate vectors. The result of `survfit` also has print, plot and summary methods that make it far more useful.

## Value

a data frame with components

<code>time</code>	The sorted vector of unique time points (those at which an event occurred)
<code>hazard</code>	The baseline hazard function
<code>strata</code>	If <code>fit</code> was a stratified Cox model, the strata. There will be one survival curve per strata.

[survfit](#)

---

`bladder`

*Bladder Cancer Recurrences*

---

## Description

Data on recurrences of bladder cancer, used by many people to demonstrate methodology for recurrent event modelling.

`Bladder1` is the full data set from the study. It contains all three treatment arms and all recurrences for 118 subjects; the maximum observed number of recurrences is 9.

`Bladder` is the data set that appears most commonly in the literature. It uses only the 85 subjects with nonzero follow-up who were assigned to either thiotepa or placebo. The status variable is 1 for recurrence and 0 for everything else (including death for any reason). The data set is laid out in the competing risks format of the paper by Wei, Lin, and Weissfeld.

`Bladder2` uses the same subset of subjects as `bladder`, but formatted in the (start, stop] or Anderson-Gill style. Note that in transforming from the WLW to the AG style data set there is a quite common programming mistake that leads to extra follow-up time for 12 subjects (all those with more than 4 recurrences); this includes some earlier releases of the data in R.

## Usage

```
bladder1
bladder
bladder2
```

**Format**

## bladder1

id: Patient id  
 treatment: Placebo, pyridoxine (vitamin B6), or thiotepa  
 number: Initial number of tumours (8=8 or more)  
 size: Size (cm) of largest initial tumour  
 recur: Number of recurrences  
 start,stop: The start and end time of each time interval  
 status: End of interval code, 0=censored, 1=recurrence,  
 2=death from bladder disease, 3=death other/unknown cause  
 rtumor: Number of tumors found at the time of a recurrence  
 rsize: Size of largest tumor at a recurrence  
 enum: Event number (observation number within patient)

## bladder

id: Patient id  
 rx: Treatment 1=placebo 2=thiotepa  
 number: Initial number of tumours (8=8 or more)  
 size: size (cm) of largest initial tumour  
 stop: recurrence or censoring time  
 enum: which recurrence (up to 4)

## bladder2

id: Patient id  
 rx: Treatment 1=placebo 2=thiotepa  
 number: Initial number of tumours (8=8 or more)  
 size: size (cm) of largest initial tumour  
 start: start of interval (0 or previous recurrence time)  
 stop: recurrence or censoring time  
 enum: which recurrence (up to 4)

## Description

Returns estimates and standard errors from relative risk regression fit to data from case-cohort studies. A choice is available among the Prentice, Self-Prentice and Lin-Ying methods for unstratified data. For stratified data the choice is between Borgan I, a generalization of the Self-Prentice estimator for unstratified case-cohort data, and Borgan II, a generalization of the Lin-Ying estimator.

## Usage

```
cch(formula, data = sys.parent(), subcoh, id, stratum=NULL, cohort.size,
    method =c("Prentice", "SelfPrentice", "LinYing", "I.Borgan", "II.Borgan"),
    robust=FALSE)
```

## Arguments

<code>formula</code>	A formula object that must have a <code>Surv</code> object as the response. The <code>Surv</code> object must be of type <code>"right"</code> , or of type <code>"counting"</code> .
<code>subcoh</code>	Vector of indicators for subjects sampled as part of the sub-cohort. Code 1 or TRUE for members of the sub-cohort, 0 or FALSE for others. If <code>data</code> is a data frame then <code>subcoh</code> may be a one-sided formula.
<code>id</code>	Vector of unique identifiers, or formula specifying such a vector.
<code>stratum</code>	A vector of stratum indicators or a formula specifying such a vector
<code>cohort.size</code>	Vector with size of each stratum original cohort from which subcohort was sampled
<code>data</code>	An optional data frame in which to interpret the variables occurring in the formula.
<code>method</code>	Three procedures are available. The default method is "Prentice", with options for "SelfPrentice" or "LinYing".
<code>robust</code>	For "LinYing" only, if <code>robust=TRUE</code> , use design-based standard errors even for phase I

## Details

Implements methods for case-cohort data analysis described by Therneau and Li (1999). The three methods differ in the choice of "risk sets" used to compare the covariate values of the failure with those of others at risk at the time of failure. "Prentice" uses the sub-cohort members "at risk" plus the failure if that occurs outside the sub-cohort and is score unbiased. "SelfPren" (Self-Prentice) uses just the sub-cohort members "at risk". These two have the same asymptotic variance-covariance matrix. "LinYing" (Lin-Ying) uses the all members of the sub-cohort and all failures outside the sub-cohort who are "at risk". The methods also differ in the weights given to different score contributions.

The `data` argument must not have missing values for any variables in the model. There must not be any censored observations outside the subcohort.

## Value

An object of class "cch" incorporating a list of estimated regression coefficients and two estimates of their asymptotic variance-covariance matrix.

<code>coef</code>	regression coefficients.
<code>naive.var</code>	Self-Prentice model based variance-covariance matrix.
<code>var</code>	Lin-Ying empirical variance-covariance matrix.

---

`clogit`*Conditional logistic regression*

---

**Description**

Estimates a logistic regression model by maximising the conditional likelihood. Uses a model formula of the form `case.status~exposure+strata(matched.set)`. The default is to use the exact conditional likelihood, a commonly used approximate conditional likelihood is provided for compatibility with older software.

**Usage**

```
clogit(formula, data, method=c("exact", "approximate"), na.action=getOption("na.
```

**Arguments**

<code>formula</code>	Model formula
<code>data</code>	data frame
<code>method</code>	correct or approximate conditonal likelihood?
<code>na.action</code>	missing value handling
<code>subset</code>	subset of records to use
<code>control</code>	control values

**Value**

An object of class "clogit", which is a wrapper for a "coxph" object.

**Author(s)**

Thomas Lumley

## Not run: clogit(case~spontaneous+induced+strata(stratum), data=infert)
```

---

cluster	<i>Identify clusters.</i>
---------	---------------------------

---

**Description**

This is a special function used in the context of survival models. It identifies correlated groups of observations, and is used on the right hand side of a formula. Using `cluster()` in a formula implies that robust sandwich variance estimators are desired.

**Usage**

```
cluster(x)
```

**Arguments**

`x` A character, factor, or numeric variable.

**Details**

The function's only action is semantic, to mark a variable as the cluster indicator. The resulting variance is what is known as the "working independence" variance in a GEE model.

**Value**

`x`

**See Also**

[coxph](#), [survreg](#)

**Examples**

```
marginal.model <- coxph(Surv(time, status) ~ rx + cluster(litter), rats)
frailty.model <- coxph(Surv(time, status) ~ rx + frailty(litter), rats)
```

---

colon	<i>Chemotherapy for Stage B/C colon cancer</i>
-------	--

---

**Description**

These are data from one of the first successful trials of adjuvant chemotherapy for colon cancer. Levamisole is a low-toxicity compound previously used to treat worm infestations in animals; 5-FU is a moderately toxic (as these things go) chemotherapy agent. There are two records per person, one for recurrence and one for death

**Usage**

```
colon
```

**Format**

id: id  
 study: 1 for all patients  
 rx: Treatment - Obs(ervation), Lev(amisole), Lev(amisole)+5-FU  
 sex: 1=male  
 age: in years  
 obstruct: obstruction of colon by tumour  
 perfor: perforation of colon  
 adhere: adherence to nearby organs  
 nodes: number of lymph nodes with detectable cancer  
 time: days until event or censoring  
 status: censoring status  
 differ: differentiation of tumour (1=well, 2=moderate, 3=poor)  
 extent: Extent of local spread (1=submucosa, 2=muscle, 3=serosa, 4=contiguous structures)  
 surg: time from surgery to registration (0=short, 1=long)  
 node4: more than 4 positive lymph nodes  
 etype: event type: 1=recurrence,2=death

cox.zph

*Test the Proportional Hazards Assumption of a Cox Regression*

---

## Description

Test the proportional hazards assumption for a Cox regression model fit (coxph).

## Usage

```
cox.zph(fit, transform="km", global=TRUE)
```

## Arguments

fit the result of fitting a Cox regression model, using the `coxph` function.  
 transform a character string specifying how the survival times should be transformed before the test is performed. Possible values are "km", "rank", "identity" or a function of one argument.  
 global should a global chi-square test be done, in addition to the per-variable tests.

## Value

an object of class "cox.zph", with components:

table a matrix with one row for each variable, and optionally a last row for the global test. Columns of the matrix contain the correlation coefficient between transformed survival time and the scaled Schoenfeld residuals, a chi-square, and the two-sided p-value. For the global test there is no appropriate correlation, so an NA is entered into the matrix as a placeholder.

<code>x</code>	the transformed time axis.
<code>y</code>	the matrix of scaled Schoenfeld residuals. There will be one column per variable and one row per event. The row labels contain the original event times (for the identity transform, these will be the same as <code>x</code> ).
<code>call</code>	the calling sequence for the routine.  The computations require the original <code>x</code> matrix of the Cox model fit. Thus it saves time if the <code>x=TRUE</code> option is used in <code>coxph</code> . This function would usually be followed by both a plot and a print of the result. The plot gives an estimate of the time-dependent coefficient $\beta(t)$ . If the proportional hazards assumption is true, $\beta(t)$ will be a horizontal line. The printout gives a test for <code>slope=0</code> .

print(temp)                # display the results
plot(temp)                 # plot curves
```

---

coxph

*Fit Proportional Hazards Regression Model*

---

## Description

Fits a Cox proportional hazards regression model. Time dependent variables, time dependent strata, multiple events per subject, and other extensions are incorporated using the counting process formulation of Andersen and Gill.

## Usage

```
coxph(formula, data=, weights, subset,
       na.action, init, control,
       method=c("efron", "breslow", "exact"),
       singular.ok=TRUE, robust=FALSE,
       model=FALSE, x=FALSE, y=TRUE, ...)
```

**Arguments**

<code>formula</code>	a formula object, with the response on the left of a <code>~</code> operator, and the terms on the right. The response must be a survival object as returned by the <code>Surv</code> function.
<code>data</code>	a <code>data.frame</code> in which to interpret the variables named in the <code>formula</code> , or in the <code>subset</code> and the <code>weights</code> argument.
<code>weights</code>	vector of case weights. If <code>weights</code> is a vector of integers, then the estimated coefficients are equivalent to estimating the model from data with the individual cases replicated as many times as indicated by <code>weights</code> .
<code>subset</code>	expression indicating which subset of the rows of data should be used in the fit. All observations are included by default.
<code>na.action</code>	a missing-data filter function. This is applied to the <code>model.frame</code> after any <code>subset</code> argument has been used. Default is <code>options()\$na.action</code> .
<code>init</code>	vector of initial values of the iteration. Default initial value is zero for all variables.
<code>control</code>	Object of class <code>coxph.control</code> specifying iteration limit and other control options. Default is <code>coxph.control(...)</code> .
<code>method</code>	a character string specifying the method for tie handling. If there are no tied death times all the methods are equivalent. Nearly all Cox regression programs use the Breslow method by default, but not this one. The Efron approximation is used as the default here, as it is much more accurate when dealing with tied death times, and is as efficient computationally. The exact method computes the exact partial likelihood, which is equivalent to a conditional logistic model. If there are a large number of ties the computational time will be excessive.
<code>singular.ok</code>	logical value indicating how to handle collinearity in the model matrix. If <code>TRUE</code> , the program will automatically skip over columns of the X matrix that are linear combinations of earlier columns. In this case the coefficients for such columns will be NA, and the variance matrix will contain zeros. For ancillary calculations, such as the linear predictor, the missing coefficients are treated as zeros.
<code>robust</code>	if <code>TRUE</code> a robust variance estimate is returned. Default is <code>TRUE</code> if the model includes a <code>cluster</code> operative, <code>FALSE</code> otherwise.
<code>model</code>	logical value: if <code>TRUE</code> , the model frame is returned in component <code>model</code> .
<code>x</code>	logical value: if <code>TRUE</code> , the model frame is returned in component <code>x</code> .
<code>y</code>	logical value: if <code>TRUE</code> , the model frame is returned in component <code>y</code> .
<code>...</code>	Other arguments will be passed to <code>coxph.control</code>

**Details**

The proportional hazards model is usually expressed in terms of a single survival time value for each person, with possible censoring. Andersen and Gill reformulated the same problem as a counting process; as time marches onward we observe the events for a subject, rather like watching a Geiger counter. The data for a subject is presented as multiple rows or "observations", each of which applies to an interval of observation (start, stop].

**Value**

an object of class "coxph" representing the fit. See `coxph.object` for details.

### Side Effects

Depending on the call, the `predict`, `residuals`, and `survfit` routines may need to reconstruct the `x` matrix created by `coxph`. Differences in the environment, such as which data frames are attached or the value of `options()$contrasts`, may cause this computation to fail or worse, to be incorrect. See the survival overview document for details.

### Special terms

There are two special terms that may be used in the model equation. A `strata` term identifies a stratified Cox model; separate baseline hazard functions are fit for each strata. The `cluster` term is used to compute a robust variance for the model. The term `+ cluster(id)` where each value of `id` is unique is equivalent to specifying the `robust=T` argument, and produces an approximate jackknife estimate of the variance. If the `id` variable were not unique, but instead identifies clusters of correlated observations, then the variance estimate is based on a grouped jackknife.

### Convergence

In certain data cases the actual MLE estimate of a coefficient is infinity, e.g., a dichotomous variable where one of the groups has no events. When this happens the associated coefficient grows at a steady pace and a race condition will exist in the fitting routine: either the log likelihood converges, the information matrix becomes effectively singular, an argument to `exp` becomes too large for the computer hardware, or the maximum number of interactions is exceeded. (Nearly always the first occurs.) The routine attempts to detect when this has happened, not always successfully. The primary consequence for the user is that the Wald statistic, `coefficient/se(coefficient)`, is not valid in this case and should be ignored; the likelihood ratio and Wald tests remain valid however.

### PENALISED REGRESSION

`coxph` can now maximise a penalised partial likelihood with arbitrary user-defined penalty. Supplied penalty functions include ridge regression ([ridge](#)), smoothing splines ([pspline](#)), and frailty models ([frailty](#)).

# Create the simplest test data set
test1 <- list(time=c(4,3,1,1,2,2,3),
             status=c(1,1,1,0,1,1,0),
             x=c(0,2,1,1,1,0,0),
             sex=c(0,0,0,0,1,1,1))
# Fit a stratified model
coxph(Surv(time, status) ~ x + strata(sex), test1)
# Create a simple data set for a time-dependent model
test2 <- list(start=c(1,2,5,2,1,7,3,4,8,8),
```

```

      stop=c(2,3,6,7,8,9,9,9,14,17),
      event=c(1,1,1,1,1,1,1,0,0,0),
      x=c(1,0,0,1,0,1,1,1,0,0))
summary(coxph(Surv(start, stop, event) ~ x, test2))

#
# Create a simple data set for a time-dependent model
#
test2 <- list(start=c(1, 2, 5, 2, 1, 7, 3, 4, 8, 8),
              stop =c(2, 3, 6, 7, 8, 9, 9, 9,14,17),
              event=c(1, 1, 1, 1, 1, 1, 1, 0, 0, 0),
              x     =c(1, 0, 0, 1, 0, 1, 1, 1, 0, 0) )

summary( coxph( Surv(start, stop, event) ~ x, test2))

# Fit a stratified model, clustered on patients

bladder1 <- bladder[bladder$enum < 5, ]
coxph(Surv(stop, event) ~ (rx + size + number) * strata(enum) +
      cluster(id), bladder1)

```

---

coxph.control

*Ancillary arguments for controlling coxph fits*

---

## Description

This is used to set various numeric parameters controlling a Cox model fit. Typically it would only be used in a call to `coxph`.

## Usage

```
coxph.control(eps = 1e-09, toler.chol = .Machine$double.eps^0.75,
              iter.max = 20, toler.inf = sqrt(eps), outer.max = 10)
```

## Arguments

<code>eps</code>	Iteration continues until the relative change in the log partial likelihood is less than <code>eps</code> . Must be positive.
<code>toler.chol</code>	Tolerance for detection of singularity during a Cholesky decomposition of the variance matrix, i.e., for detecting a redundant predictor variable.
<code>iter.max</code>	Maximum number of iterations to attempt for convergence.
<code>toler.inf</code>	Tolerance criteria for the warning message about a possible infinite coefficient value.
<code>outer.max</code>	For a penalized coxph model, e.g. with pspline terms, there is an outer loop of iteration to determine the penalty parameters; maximum number of iterations for this outer loop.

## Value

a list containing the values of each of the above constants

**Author(s)**

Terry Therneau

**See Also**[coxph](#)

coxph.detail

*Details of a Cox Model Fit***Description**

Returns the individual contributions to the first and second derivative matrix, at each unique event time.

**Usage**

```
coxph.detail(object, riskmat=FALSE)
```

**Arguments**

object	a Cox model object, i.e., the result of <code>coxph</code> .
riskmat	include the at-risk indicator matrix in the output?

**Details**

This function may be useful for those who wish to investigate new methods or extensions to the Cox model. The example below shows one way to calculate the Schoenfeld residuals.

**Value**

a list with components

time	the vector of unique event times
nevent	the number of events at each of these time points.
means	a matrix with one row for each event time and one column for each variable in the Cox model, containing the weighted mean of the variable at that time, over all subjects still at risk at that time. The weights are the risk weights $\exp(x \%*\% \text{fit}\$\text{coef})$ .
nrisk	number of subjects at risk.
hazard	the hazard increment.
score	the contribution to the score vector (first derivative of the log partial likelihood) at each time point.
imat	the contribution to the information matrix (second derivative of the log partial likelihood) at each time point.
varhaz	the variance of the hazard increment.
x, y	copies of the input data.
strata	only present for a stratified Cox model, this is a table giving the number of time points of component <code>time</code> that were contributed by each of the strata.

`riskmat` a matrix with one row for each time and one column for each observation containing a 0/1 value to indicate whether that observation was (1) or was not (0) at risk at the given time point.

### Examples

```
fit <- coxph(Surv(futime,fustat) ~ age + rx + ecog.ps, ovarian, x=TRUE)
fitd <- coxph.detail(fit)
events <- fit$y[,2]==1
etime <- fit$y[events,1] #the event times --- may have duplicates
indx <- match(etime, fitd$time)
sresid <- fit$x[events,] - fitd$means[indx,]
```

---

coxph.object

*Proportional Hazards Regression Object*

---

### Description

This class of objects is returned by the `coxph` class of functions to represent a fitted proportional hazards model. Objects of this class have methods for the functions `print`, `summary`, `residuals`, `predict` and `survfit`.

### Arguments

`coefficients` the coefficients of the linear predictor, which multiply the columns of the model matrix. If the model is over-determined there will be missing values in the vector corresponding to the redundant columns in the model matrix.

`var` the variance matrix of the coefficients. Rows and columns corresponding to any missing coefficients are set to zero.

`naive.var` this component will be present only if the `robust` option was true. If so, the `var` component will contain the robust estimate of variance, and this component will contain the ordinary estimate.

`loglik` a vector of length 2 containing the log-likelihood with the initial values and with the final values of the coefficients.

`score` value of the efficient score test, at the initial value of the coefficients.

`rscore` the robust log-rank statistic, if a robust variance was requested.

`wald.test` the Wald test of whether the final coefficients differ from the initial values.

`iter` number of iterations used.

`linear.predictors` the vector of linear predictors, one per subject.

`residuals` the martingale residuals.

`means` vector of column means of the X matrix. Subsequent survival curves are adjusted to this value.

`n` the number of observations used in the fit.

<code>weights</code>	the vector of case weights, if one was used.
<code>method</code>	the computation method used.
<code>na.action</code>	the <code>na.action</code> attribute, if any, that was returned by the <code>na.action</code> routine. The object will also contain the following, for documentation see the <code>lm</code> object: <code>terms</code> , <code>assign</code> , <code>formula</code> , <code>call</code> , and, optionally, <code>x</code> , <code>y</code> , and/or <code>frame</code> .

### Components

The following components must be included in a legitimate `coxph` object.

### See Also

---

dsurvreg

*Distributions available in survreg.*

---

### Description

Density, cumulative probability, and quantiles for the set of distributions supported by the `survreg` function.

### Usage

```
dsurvreg(x, mean, scale=1, distribution='weibull', parms)
psurvreg(q, mean, scale=1, distribution='weibull', parms)
qsurvreg(p, mean, scale=1, distribution='weibull', parms)
```

### Arguments

<code>x</code>	vector of quantiles. Missing values (NAs) are allowed.
<code>q</code>	vector of quantiles. Missing values (NAs) are allowed.
<code>p</code>	vector of probabilities. Missing values (NAs) are allowed.
<code>mean</code>	vector of means. This is replicated to be the same length as <code>p</code> or <code>q</code> .
<code>scale</code>	vector of (positive) scale factors. This is replicated to be the same length as <code>p</code> or <code>q</code> .
<code>distribution</code>	character string giving the name of the distribution. This must be one of the elements of <code>survreg.distributions</code>
<code>parms</code>	optional parameters, if any, of the distribution. For the t-distribution this is the degrees of freedom.

### Details

Elements of `q` or `p` that are missing will cause the corresponding elements of the result to be missing.

The `mean` and `scale` values are as they would be for `survreg`. In particular, if the distribution is one that involves a transformation, then they are the mean and scale of the transformed distribution. For example, the Weibull distribution is fit using the Extreme value distribution along with a log transformation. Letting  $F(t) = 1 - \exp[-(at)^p]$  be the cumulative distribution of the Weibull, the mean corresponds to  $-\log(a)$  and the scale to  $1/p$  (Kalbfleish and Prentice, section 2.2.2).

**Value**

density (`dsurvreg`), probability (`psurvreg`), quantile (`qsurvreg`), or for the requested distribution with mean and scale parameters `mean` and `sd`.

**References**

Kalbfleish, J. D. and Prentice, R. L. (1970). *The Statistical Analysis of Failure Time Data* Wiley, New York.

## End(Not run)
```

---

frailty

*Random effects terms*

---

**Description**

The frailty function allows one to add a simple random effects term to a Cox or survreg model.

**Usage**

```
frailty(x, distribution="gamma", ...)
frailty.gamma(x, sparse = (nclass > 5), theta, df, eps = 1e-05, method = c("em",
frailty.gaussian(x, sparse = (nclass > 5), theta, df, method = c("reml", "aic", "d
frailty.t(x, sparse = (nclass > 5), theta, df, eps = 1e-05, tdf = 5, method = c("
```

**Arguments**

<code>x</code>	the variable to be entered as a random effect. It is always treated as a factor.
<code>distribution</code>	either the <code>gamma</code> , <code>gaussian</code> or <code>t</code> distribution may be specified. The routines <code>frailty.gamma</code> , <code>frailty.gaussian</code> and <code>frailty.t</code> do the actual work.
<code>...</code>	Arguments for specific distribution, including (but not limited to)
<code>sparse</code>	cutoff for using a sparse coding of the data matrix. If the total number of levels of <code>x</code> is larger than this value, then a sparse matrix approximation is used. The correct cutoff is still a matter of exploration: if the number of levels is very large (thousands) then the non-sparse calculation may not be feasible in terms of both memory and compute time. Likewise, the accuracy of the sparse approximation appears to be related to the maximum proportion of subjects in any one class, being best when no one class has a large membership.
<code>theta</code>	if specified, this fixes the variance of the random effect. If not, the variance is a parameter, and a best solution is sought. Specifying this implies <code>method='fixed'</code> .
<code>df</code>	if specified, this fixes the degrees of freedom for the random effect. Specifying this implies <code>method='df'</code> . Only one of <code>theta</code> or <code>df</code> should be specified.
<code>method</code>	the method used to select a solution for <code>theta</code> , the variance of the random effect. The <code>fixed</code> corresponds to a user-specified value, and no iteration is done. The <code>df</code> selects the variance such that the degrees of freedom for the random effect matches a user specified value. The <code>aic</code> method seeks to maximize Akiake's information criteria $2*(\text{partial likelihood} - \text{df})$ . The <code>ml</code> and <code>reml</code> methods are specific to Cox models with <code>gamma</code> and <code>gaussian</code> random effects, respectively. Please see further discussion below.
<code>tdf</code>	the degrees of freedom for the <code>t</code> -distribution.
<code>eps</code>	convergence criteria for the iteration on <code>theta</code> .

**Details**

The `frailty` plugs into the general penalized modeling framework provided by the `coxph` and `survreg` routines. This framework deals with likelihood, penalties, and degrees of freedom; these aspects work well with either parent routine.

Therneau, Grambsch, and Pankratz show how maximum likelihood estimation for the Cox model with a `gamma` frailty can be accomplished using a general penalized routine, and Ripatti and Palmgren work through a similar argument for the Cox model with a `gaussian` frailty. Both of these are specific to the Cox model. Use of `gamma/ml` or `gaussian/reml` with `survreg` does not lead to valid results.

The extensible structure of the penalized methods is such that the penalty function, such as `frailty` or `pspine`, is completely separate from the modeling routine. The strength of this is that a user can plug in any penalization routine they choose. A weakness is that it is very difficult for the modeling routine to know whether a sensible penalty routine has been supplied.

For Cox models the `coxme` package has replaced superseded this method.

**Value**

this function is used in the model statement of either `coxph` or `survreg`. It's results are used internally.

---

is.ratetable	Verify that an object is of class ratetable.
--------------	--

---

### Description

The function verifies not only the `class` attribute, but the structure of the object.

### Usage

```
is.ratetable(x, verbose=FALSE)
```

### Arguments

x	the object to be verified.
verbose	if TRUE and the object is not a ratetable, then return a character string describing the way(s) in which x fails to be a proper ratetable object.

### Details

Rate tables are used by the `pyears` and `survexp` functions, and normally contain death rates for some population, categorized by age, sex, or other variables. They have a fairly rigid structure, and the `verbose` option can help in creating a new rate table.

### Value

returns TRUE if x is a ratetable, and FALSE or a description if it is not.

### See Also

[pyears](#), [survexp](#).

### Examples

```
is.ratetable(survexp.us) # True
is.ratetable(cancer)    # False
```

---

 kidney

*Kidney catheter data*

---

### Description

Data on the recurrence times to infection, at the point of insertion of the catheter, for kidney patients using portable dialysis equipment. Catheters may be removed for reasons other than infection, in which case the observation is censored. Each patient has exactly 2 observations.

This data has often been used to illustrate the use of random effects (frailty) in a survival model. However, one of the males (id 21) is a large outlier, with much longer survival than his peers. If this observation is removed no evidence remains for a random subject effect.

### Format

```

patient:  id
time:    time
status:  event status
age:     in years
sex:     1=male, 2=female
disease: disease type (0=GN, 1=AN, 2=PKD, 3=Other)
frail:   frailty estimate from original paper
  
```

### Note

The original paper ignored the issue of tied times and so is not exactly reproduced by the survival package.

### Source

CA McGilchrist, CW Aisbett (1991), Regression with frailty in survival analysis. *Biometrics* **47**, 461–66.

### Examples

```

kfit <- coxph(Surv(time, status)~ age + sex + disease + frailty(id), kidney)
kfit0 <- coxph(Surv(time, status)~ age + sex + disease, kidney)
kfitml <- coxph(Surv(time, status) ~ age + sex + disease +
  frailty(id, dist='gauss'), kidney)
  
```

---

 lines.survfit

*Add Lines or Points to a Survival Plot*

---

### Description

Often used to add the expected survival curve(s) to a Kaplan-Meier plot generated with `plot.survfit`.

**Usage**

```
## S3 method for class 'survfit':
lines(x, type="s", mark=3, col=1, lty=1,
      lwd=1, mark.time=TRUE,
      xscale=1, firstx=0, firsty=1, xmax, fun, conf.int=FALSE, ...)
## S3 method for class 'survfit':
points(x, ...)
```

**Arguments**

<code>x</code>	a survival object, generated from the <code>survfit</code> or <code>survexp</code> functions.
<code>type</code>	the line type, as described in <code>lines</code> . The default is a step function for <code>survfit</code> objects, and a connected line for <code>survexp</code> objects.
<code>mark, col, lty, lwd</code>	vectors giving the mark symbol, color, line type and line width for the added curves.
<code>...</code>	other graphical parameters
<code>mark.time</code>	controls the labeling of the curves. If <code>FALSE</code> , no labeling is done. If <code>TRUE</code> , then curves are marked at each censoring time. If <code>mark.time</code> is a numeric vector, then curves are marked at the specified time points.
<code>xscale</code>	a number used to divide the x values. If time was originally in days, a value of 365.25 would give a plotted scale in years.
<code>firstx, firsty</code>	the starting point for the survival curves. If either of these is set to <code>NA</code> or <code>&lt;</code> blank <code>&gt;</code> the plot will start at the first time point of the curve.
<code>xmax</code>	the maximum horizontal plot coordinate. This shortens the curve before plotting it, so unlike using the <code>xlim</code> graphical parameter, warning messages about out of bounds points are not generated.
<code>fun</code>	an arbitrary function defining a transformation of the survival curve. For example <code>fun=log</code> is an alternative way to draw a log-survival curve (but with the axis labeled with $\log(S)$ values). Four often used transformations can be specified with a character argument instead: "log" is the same as using the <code>log=T</code> option, "event" plots cumulative events ( $f(y) = 1-y$ ), "cumhaz" plots the cumulative hazard function ( $f(y) = -\log(y)$ ) and "cloglog" creates a complimentary log-log survival plot ( $f(y) = \log(-\log(y))$ along with log scale for the x-axis).
<code>conf.int</code>	if <code>TRUE</code> , confidence bands for the curves are also plotted. If set to "only", then only the CI bands are plotted, and the curve itself is left off. This can be useful for fine control over the colors or line types of a plot.

**Value**

a list with components `x` and `y`, containing the coordinates of the last point on each of the curves (but not of the confidence limits). This may be useful for labeling.

**Side Effects**

one or more curves are added to the current plot.

**See Also**

 mgus

*Monoclonal gammopathy data*

---

## Description

Natural history of 241 subjects with monoclonal gammopathy of undetermined significance (MGUS).

## Usage

mgus  
mgus1  
mgus2

## Format

mgus: A data frame with 241 observations on the following 12 variables.

id: subject id  
 age: age in years  
 sex: male or female  
 dxyr: year of diagnosis  
 pcdx: for subjects who progress to a plasma cell malignancy  
 the subtype of malignancy: multiple myeloma (MM) is the most common, followed by amyloidosis (AM), macroglobulinemia (MA), and other lymphoprolifative (LP)  
 pctime: days from MGUS until diagnosis of a plasma cell malignancy  
 futime: days from diagnosis to last follow-up  
 death: 1= follow-up is until death  
 alb: albumin level at MGUS diagnosis  
 creat: creatinine at MGUS diagnosis  
 hgb: hemoglobin at MGUS diagnosis  
 mspike: size of the monoclonal protien spike at diagnosis

mgus1: The same data set in start,stop format. Contains the id, age, sex, and laboratory variable described above along with

start, stop: sequential intervals of time for each subject  
 status: =1 if the interval ends in an event  
 event: the event type

mgus2: The mgus data, but formatted in the competing risks style. Each subject has three observa-

tions, one for time to death, one for time to MM, and one for time to a PC malignancy other than MM. Contains the id, age, sex, and laboratory variable described above along with

time: time to event or censoring  
 status: 1 if the event occurred, 0 otherwise  
 event: death, myeloma, or other

### Details

Plasma cells are responsible for manufacturing immunoglobulins, an important part of the immune defense. At any given time there are estimated to be about  $10^6$  different immunoglobulins in the circulation at any one time. When a patient has a plasma cell malignancy the distribution will become dominated by a single isotype, the product of the malignant clone, visible as a spike on a serum protein electrophoresis. Monoclonal gammopathy of undetermined significance (MGUS) is the presence of such a spike, but in a patient with no evidence of overt malignancy. This data set of 241 sequential subjects at Mayo Clinic was the groundbreaking study defining the natural history of such subjects.

model.frame.coxph *Model.frame method for coxph objects*

---

### Description

Recreate the model frame of a coxph fit.

### Usage

```
## S3 method for class 'coxph':
model.frame(formula, ...)
```

### Arguments

formula      the result of a coxph fit  
 ...          other arguments to model.frame

### Details

For details, see the manual page for the generic function. This function would rarely be called by a user, it is mostly used inside functions like `residual` that need to recreate the data set from a model in order to do further calculations.

**Value**

the model frame used in the original fit, or a parallel one for new data.

**Author(s)**

Terry Therneau

**See Also**

**Examples**

```
fit1 <- coxph(Surv(time, status) ~ age + factor(ph.ecog), data=lung)
linear.predictor <- model.matrix(fit1)

fit2 <- coxph(Surv(time, status) ~ age + factor(ph.ecog), data=lung,
              x=TRUE)
all.equal(model.matrix(fit1), fit2$x)
```

nwtco

*Data from the National Wilms's Tumor Study***Description**

Missing data/measurement error example. Tumor histology predicts survival, but prediction is stronger with central lab histology than with the local institution determination.

**Usage**

```
nwtco
```

**Format**

A data frame with 4028 observations on the following 9 variables.

```
seqno id number
instit Histology from local institution
histol Histology from central lab
stage Disease stage
study study
rel indicator for relapse
edrel time to relapse
age age in months
in.subcohort Included in the subcohort for the example in the paper
```

pbc

*Mayo Clinic Primary Biliary Cirrhosis Data*

---

### Description

D This data is from the Mayo Clinic trial in primary biliary cirrhosis (PBC) of the liver conducted between 1974 and 1984. A total of 424 PBC patients, referred to Mayo Clinic during that ten-year interval, met eligibility criteria for the randomized placebo controlled trial of the drug D-penicillamine. The first 312 cases in the data set participated in the randomized trial and contain largely complete data. The additional 112 cases did not participate in the clinical trial, but consented to have basic measurements recorded and to be followed for survival. Six of those cases were lost to follow-up shortly after diagnosis, so the data here are on an additional 106 cases as well as the 312 randomized participants.

A nearly identical data set found in appendix D of Fleming and Harrington; this version has fewer missing values.

**Usage**

pbc

**Format**

age: in years  
 albumin: serum albumin (mg/dl)  
 alk.phos: alkaline phosphatase (U/liter)  
 ascites: presence of ascites  
 ast: aspartate aminotransferase, once called SGOT (U/ml)  
 bili: serum bilirubin (mg/dl)  
 chol: serum cholesterol (mg/dl)  
 copper: urine copper (ug/day)  
 edema: 0 no edema, 0.5 untreated or successfully treated  
         1 edema despite diuretic therapy  
 hepato: presence of hepatomegaly or enlarged liver  
 id: case number  
 platelet: platelet count  
 protime: standardised blood clotting time  
 sex: m/f  
 spiders: blood vessel malformations in the skin  
 stage: histologic stage of disease (needs biopsy)  
 status: status at endpoint, 0/1/2 for censored, transplant, dead  
 time: number of days between registration and the earlier of death,  
        transplantation, or study analysis in July, 1986  
 trt: 1/2/NA for D-penicillmain, placebo, not randomised  
 trig: triglycerides (mg/dl)

pbcseq

*Mayo Clinic Primary Biliary Cirrhosis, sequential data***Description**

This data is a continuation of the PBC data set, and contains the follow-up laboratory data for each study patient. An analysis based on the data can be found in Murtagh, et. al.

The primary PBC data set contains only baseline measurements of the laboratory paramters. This data set contains multiple laboratory results, but only on the 312 randomized patients. Some baseline data values in this file differ from the original PBC file, for instance, the data errors in prothrombin time and age which were discovered after the original analysis (see Fleming and Harrington, figure 4.6.7).

One "feature" of the data deserves special comment. The last observation before death or liver transplant often has many more missing covariates than other data rows. The original clinical protocol for these patients specified visits at 6 months, 1 year, and annually thereafter. At these protocol visits lab values were obtained for a large pre-specified battery of tests. "Extra" visits, often undertaken because of worsening medical condition, did not necessarily have all this lab work. The missing values are thus potentially informative.

## Usage

pbc

## Format

id:	case number
age:	in years
sex:	m/f
trt:	1/2/NA for D-penicillmain, placebo, not randomised
time:	number of days between registration and the earlier of death, transplantation, or study analysis in July, 1986
status:	status at endpoint, 0/1/2 for censored, transplant, dead
day:	number of days between enrollment and this visit date all measurements below refer to this date
albumin:	serum albumin (mg/dl)
alk.phos:	alkaline phosphatase (U/liter)
ascites:	presence of ascites
ast:	aspartate aminotransferase, once called SGOT (U/ml)
bili:	serum bilirubin (mg/dl)
chol:	serum cholesterol (mg/dl)
copper:	urine copper (ug/day)
edema:	0 no edema, 0.5 untreated or successfully treated 1 edema despite diuretic therapy
hepato:	presence of hepatomegaly or enlarged liver
platelet:	platelet count
protime:	standardised blood clotting time
spiders:	blood vessel malformations in the skin
stage:	histologic stage of disease (needs biopsy)
trig:	triglycerides (mg/dl)

---

plot.aareg                      *Plot an aareg object.*

---

### Description

Plot the estimated coefficient function(s) from a fit of Aalen's additive regression model.

### Usage

```
## S3 method for class 'aareg':
plot(x, se=TRUE, maxtime, type='s', ...)
```

### Arguments

x	the result of a call to the aareg function
se	if TRUE, standard error bands are included on the plot
maxtime	upper limit for the x-axis.
type	graphical parameter for the type of line, default is "steps".
...	other graphical parameters such as line type, color, or axis labels.

### Side Effects

A plot is produced on the current graphical device.

### References

Aalen, O.O. (1989). A linear regression model for the analysis of life times. *Statistics in Medicine*, 8:907-925.

### See Also

aareg

---

plot.cox.zph                      *Graphical Test of Proportional Hazards*

---

### Description

Displays a graph of the scaled Schoenfeld residuals, along with a smooth curve.

### Usage

```
## S3 method for class 'cox.zph':
plot(x, resid=TRUE, se=TRUE, df=4, nsmo=40, var, ...)
```

**Arguments**

x	result of the <code>cox.zph</code> function.
resid	a logical value, if <code>TRUE</code> the residuals are included on the plot, as well as the smooth fit.
se	a logical value, if <code>TRUE</code> , confidence bands at two standard errors will be added.
df	the degrees of freedom for the fitted natural spline, <code>df=2</code> leads to a linear fit.
nsmo	number of points used to plot the fitted spline.
var	the set of variables for which plots are desired. By default, plots are produced in turn for each variable of a model. Selection of a single variable allows other features to be added to the plot, e.g., a horizontal line at zero or a main title. This has been superseded by a subscripting method; see the example below.
...	additional graphical arguments passed to the <code>plot</code> function.

**Side Effects**

a plot is produced on the current graphics device.

**See Also**

[coxph](#), [cox.zph](#).

**Examples**

```
vfit <- coxph(Surv(time,status) ~ trt + factor(celltype) +
             karno + age, data=veteran, x=TRUE)
temp <- cox.zph(vfit)
plot(temp, var=5)      # Look at Karnofsky score, old way of doing plot
plot(temp[5])         # New way with subscripting
abline(0, 0, lty=3)
# Add the linear fit as well
abline(lm(temp$y[,5] ~ temp$x)$coefficients, lty=4, col=3)
title(main="VA Lung Study")
```

---

plot.survfit

*Plot Method for 'survfit'*

---

**Description**

A plot of survival curves is produced, one curve for each strata. The `log=T` option does extra work to avoid `log(0)`, and to try to create a pleasing result. If there are zeros, they are plotted by default at 0.8 times the smallest non-zero value on the curve(s).

**Usage**

```
## S3 method for class 'survfit':
plot(x, conf.int=, mark.time=TRUE,
     mark=3, col=1, lty=1, lwd=1, cex=1, log=FALSE, xscale=1, yscale=1,
     firstx=0, firsty=1, xmax, ymin=0, fun,
     xlab="", ylab="", xaxs="S", ...)
```

**Arguments**

<code>x</code>	an object of class <code>survfit</code> , usually returned by the <code>survfit</code> function.
<code>conf.int</code>	determines whether confidence intervals will be plotted. The default is to do so if there is only 1 curve, i.e., no strata.
<code>mark.time</code>	controls the labeling of the curves. If set to <code>FALSE</code> , no labeling is done. If <code>TRUE</code> , then curves are marked at each censoring time which is not also a death time. If <code>mark.time</code> is a numeric vector, then curves are marked at the specified time points.
<code>mark</code>	vector of mark parameters, which will be used to label the curves. The <code>lines</code> help file contains examples of the possible marks. The vector is reused cyclically if it is shorter than the number of curves.
<code>col</code>	a vector of integers specifying colors for each curve. The default value is 1.
<code>lty</code>	a vector of integers specifying line types for each curve. The default value is 1.
<code>lwd</code>	a vector of numeric values for line widths. The default value is 1.
<code>cex</code>	a numeric value specifying the size of the marks. This is not treated as a vector; all marks have the same size.
<code>log</code>	a logical value, if <code>TRUE</code> the y axis will be on a log scale. Alternately, one of the standard character strings "x", "y", or "xy" can be given to specific logarithmic horizontal and/or vertical axes.
<code>yscale</code>	a numeric value used to multiply the labels on the y axis. A value of 100, for instance, would be used to give a percent scale. Only the labels are changed, not the actual plot coordinates, so that adding a curve with <code>"lines(surv.exp(...))"</code> , say, will perform as it did without the <code>yscale</code> argument.
<code>xscale</code>	a numeric value used like <code>yscale</code> for labels on the x axis. A value of 365.25 will give labels in years instead of the original days.
<code>firstx, firsty</code>	the starting point for the survival curves. If either of these is set to <code>NA</code> the plot will start at the first time point of the curve. By default, the plot program obeys tradition by having the plot start at (0,0). If <code>start.time</code> argument is used in <code>survfit</code> , <code>firstx</code> is set to that value.
<code>xmax</code>	the maximum horizontal plot coordinate. This can be used to shrink the range of a plot. It shortens the curve before plotting it, so that unlike using the <code>xlim</code> graphical parameter, warning messages about out of bounds points are not generated.
<code>ymin</code>	lower boundary for y values. Survival curves are most often drawn in the range of 0-1, even if none of the curves approach zero. The parameter is ignored if the <code>fun</code> argument is present, or if it has been set to <code>NA</code> .
<code>fun</code>	an arbitrary function defining a transformation of the survival curve. For example <code>fun=log</code> is an alternative way to draw a log-survival curve (but with the axis labeled with $\log(S)$ values), and <code>fun=sqrt</code> would generate a curve on square root scale. Four often used transformations can be specified with a character argument instead: "log" is the same as using the <code>log=T</code> option, "event" plots cumulative events ( $f(y) = 1-y$ ), "cumhaz" plots the cumulative hazard function ( $f(y) = -\log(y)$ ), and "cloglog" creates a complimentary log-log survival plot ( $f(y) = \log(-\log(y))$ ) along with log scale for the x-axis.
<code>xlab</code>	label given to the x-axis.

ylab	label given to the y-axis.
xaxis	either "S" for a survival curve or a standard x axis style as listed in <code>par</code> . Survival curves are usually displayed with the curve touching the y-axis, but not touching the bounding box of the plot on the other 3 sides. Type "S" accomplishes this by manipulating the plot range and then using the "i" style internally.
...	for future methods

**Value**

a list with components `x` and `y`, containing the coordinates of the last point on each of the curves (but not the confidence limits). This may be useful for labeling.

**Bugs**

Survival curve objects created from a `coxph` model does not include the censoring times. Therefore, specifying `mark.time=T` does not work. If you want to mark censoring times on the curve(s) resulting from a `coxph` fit, provide a vector of times as the `mark.time` argument in the call to `plot.survfit` or `lines.survfit`.

**See Also**

`par`, `survfit`, `lines.survfit`.

**Examples**

```
leukemia.surv <- survfit(Surv(time, status) ~ x, data = aml)
plot(leukemia.surv, lty = 2:3)
legend(100, .9, c("Maintenance", "No Maintenance"), lty = 2:3)
title("Kaplan-Meier Curves\nfor AML Maintenance Study")
lsurv2 <- survfit(Surv(time, status) ~ x, aml, type='fleming')
plot(lsurv2, lty=2:3, fun="cumhaz",
     xlab="Months", ylab="Cumulative Hazard")
```

---

predict.coxph

*Predictions for a Cox model*

---

**Description**

Compute fitted values and regression terms for a model fitted by `coxph`

**Usage**

```
## S3 method for class 'coxph':
predict(object, newdata,
       type=c("lp", "risk", "expected", "terms"),
       se.fit=FALSE, na.action=na.pass, terms=names(object$assign), collapse, ...)
```

**Arguments**

object	the results of a coxph fit.
newdata	Optional new data at which to do predictions. If absent predictions are for the data frame used in the original fit.
type	the type of predicted value. Choices are the linear predictor ("lp"), the risk score exp(lp) ("risk"), the expected number of events given the covariates and follow-up time ("expected"), and the terms of the linear predictor ("terms").
se.fit	if TRUE, pointwise standard errors are produced for the predictions.
na.action	applies only when the newdata argument is present, and defines the missing value action for the new data. The default is to include all observations.
terms	if type="terms", this argument can be used to specify which terms should be included; the default is all.
collapse	optional vector of subject identifiers. If specified, the output will contain one entry per subject rather than one entry per observation.
...	For future methods

**Value**

a vector or matrix of predictions, or a list containing the predictions (element "fit") and their standard errors (element "se.fit") if the se.fit option is TRUE.

**See Also**

[predict.coxph](#), [termplot](#)

**Examples**

```
fit <- coxph(Surv(time, status) ~ age + ph.ecog + strata(inst), lung)
mresid <- lung$status - predict(fit, type='expected') #Martingale resid
predict(fit, type="lp")
predict(fit, type="risk")
predict(fit, type="expected")
predict(fit, type="terms")
predict(fit, type="lp", se.fit=TRUE)
predict(fit, type="risk", se.fit=TRUE)
predict(fit, type="expected", se.fit=TRUE)
predict(fit, type="terms", se.fit=TRUE)
```

---

predict.survreg      *Predicted Values for a 'survreg' Object*

---

**Description**

Predicted values for a survreg object

**Usage**

```
## S3 method for class 'survreg':
predict(object, newdata,
        type=c("response", "link", "lp", "linear", "terms", "quantile",
              "uquantile"),
        se.fit=FALSE, terms=NULL, p=c(0.1, 0.9), na.action=na.pass, ...)
```

**Arguments**

object	result of a model fit using the <code>survreg</code> function.
newdata	data for prediction. If absent predictions are for the subjects used in the original fit.
type	the type of predicted value. This can be on the original scale of the data (response), the linear predictor ("linear", with "lp" as an allowed abbreviation), a predicted quantile on the original scale of the data ("quantile"), a quantile on the linear predictor scale ("uquantile"), or the matrix of terms for the linear predictor ("terms"). At this time "link" and linear predictor ("lp") are identical.
se.fit	if TRUE, include the standard errors of the prediction in the result.
terms	subset of terms. The default for residual type "terms" is a matrix with one column for every term (excluding the intercept) in the model.
p	vector of percentiles. This is used only for quantile predictions.
na.action	applies only when the <code>newdata</code> argument is present, and defines the missing value action for the new data. The default is to include all observations.
...	for future methods

**Value**

a vector or matrix of predicted values.

**References**

Escobar and Meeker (1992). Assessing influence in regression analysis with censored data. *Biometrics*, 48, 507-528.

**See Also**

[survreg](#), [residuals.survreg](#)

**Examples**

```
# Draw figure 1 from Escobar and Meeker
fit <- survreg(Surv(time,status) ~ age + age^2, data=stanford2,
              dist='lognormal')
plot(stanford2$age, stanford2$time, xlab='Age', ylab='Days',
     xlim=c(0,65), ylim=c(.01, 10^6), log='y')
pred <- predict(fit, newdata=list(age=1:65), type='quantile',
              p=c(.1, .5, .9))
matlines(1:65, pred, lty=c(2,1,2), col=1)

# Predicted Weibull survival curve for a lung cancer subject with
# ECOG score of 2
```

```

lfit <- survreg(Surv(time, status) ~ ph.ecog, data=lung)
pct <- 1:98/100 # The 100th percentile of predicted survival is at +infinity
ptime <- predict(lfit, newdata=data.frame(ph.ecog=2), type='quantile',
                p=pct, se=TRUE)
matplot(cbind(ptime$fit, ptime$fit + 2*ptime$se.fit,
              ptime$fit - 2*ptime$se.fit)/30.5, 1-pct,
        xlab="Months", ylab="Survival", type='l', lty=c(1,2,2), col=1)

```

---

```
print.aareg      Print an aareg object
```

---

## Description

Print out a fit of Aalen's additive regression model

## Usage

```
## S3 method for class 'aareg':
print(x, maxtime, test=c("aalen", "nrisk"), scale=1, ...)
```

## Arguments

<code>x</code>	the result of a call to the <code>aareg</code> function
<code>maxtime</code>	the upper time point to be used in the test for non-zero slope
<code>test</code>	the weighting to be used in the test for non-zero slope. The default weights are based on the variance of each coefficient, as a function of time. The alternative weight is proportional to the number of subjects still at risk at each time point.
<code>scale</code>	scales the coefficients. For some data sets, the coefficients of the Aalen model will be very small ( $10^{-4}$ ); this simply multiplies the printed values by a constant, say $1e6$ , to make the printout easier to read.
<code>...</code>	for future methods

## Details

The estimated increments in the coefficient estimates can become quite unstable near the end of follow-up, due to the small number of observations still at risk in a data set. Thus, the test for slope will sometimes be more powerful if this last 'tail' is excluded.

## Value

the calling argument is returned.

## Side Effects

the results of the fit are displayed.

`print.summary.coxph`*Print method for summary.coxph objects*

---

**Description**

Produces a printed summary of a fitted coxph model

**Usage**

```
## S3 method for class 'summary.coxph':
print(x, digits=max(getOption("digits") - 3, 3),
      signif.stars = getOption("show.signif.stars"), ...)
```

**Arguments**

<code>x</code>	the result of a call to <code>summary.coxph</code>
<code>digits</code>	significant digits to print
<code>signif.stars</code>	Show stars to highlight small p-values
<code>...</code>	For future methods

---

`print.summary.survfit`*Print Survfit Summary*

---

**Description**Prints the result of `summary.survfit`.**Usage**

```
## S3 method for class 'summary.survfit':
print(x, digits = max(options() $digits-4, 3), ...)
```

**Arguments**

<code>x</code>	an object of class "summary.survfit", which is the result of the <code>summary.survfit</code> function.
<code>digits</code>	the number of digits to use in printing the numbers.
<code>...</code>	for future methods

**Value**

x, with the invisible flag set to prevent printing.

**Side Effects**

prints the summary created by `summary.survfit`.

**See Also**

`options`, `print`, `summary.survfit`.

---

`print.survfit`      *Print a Short Summary of a Survival Curve*

---

**Description**

Print number of observations, number of events, the restricted mean survival and its standard error, and the median survival with confidence limits for the median.

**Usage**

```
## S3 method for class 'survfit':
print(x, scale=1, digits = max(options()$digits - 4, 3),
      print.rmean=getOption("survfit.print.rmean"),
      rmean = getOption('survfit.rmean'),...)
```

**Arguments**

<code>x</code>	the result of a call to the <code>survfit</code> function.
<code>scale</code>	a numeric value to rescale the survival time, e.g., if the input data to <code>survfit</code> were in days, <code>scale=365</code> would scale the printout to years.
<code>digits</code>	Number of digits to print
<code>print.rmean, rmean</code>	Options for computation and display of the restricted mean.
<code>...</code>	for future results

**Details**

The mean and its variance are based on a truncated estimator. That is, if the last observation(s) is not a death, then the survival curve estimate does not go to zero and the mean is undefined. There are four possible approaches, which are selected by the `rmean` option. The first is to set the upper limit to a constant, e.g., `rmean=365`. In this case the reported mean would be the expected number of days, out of the first 365, that would be experienced by each group. This is useful if interest focuses on a fixed period. Other options are `"none"` (no estimate), `"common"` and `"individual"`. For the last of these, the mean is computed as the area under the curve, over the range from 0 to the maximum observed time for that curve. Since the end point is random, values for different curves are not comparable and the printed standard errors are an underestimate as they do not take into account this random variation. This option is provided mainly for backwards compatibility, as this estimate was the default (only) one in earlier releases of the code. The `"common"` option uses the maximum time for all curves in the object as a common upper limit for the auc calculation.

The median and its confidence interval are defined by drawing a horizontal line at 0.5 on the plot of the survival curve and its confidence bands. The intersection of the line with the lower CI band defines the lower limit for the median's interval, and similarly for the upper band. If any of the intersections is not a point, then we use the smallest point of intersection, e.g., if the survival curve were exactly equal to 0.5 over an interval.

**Value**

`x`, with the invisible flag set to prevent printing.

**Side Effects**

he number of observations, the number of events, the median survival with its confidence interval, and optionally the restricted mean survival (`rmean`) and its standard error, are printed. If there are multiple curves, there is one line of output for each.

**See Also**

[summary.survfit](#).

---

pspline

*Smoothing splines using a pspline basis*

---

**Description**

Specifies a penalised spline basis for the predictor. This is done by fitting a comparatively small set of splines and penalising the integrated second derivative. Traditional smoothing splines use one basis per observation, but several authors have pointed out that the final results of the fit are indistinguishable for any number of basis functions greater than about 2-3 times the degrees of freedom. Eilers and Marx point out that if the basis functions are evenly spaced, this leads to significant computational simplifications.

**Usage**

```
pspline(x, df=4, theta, nterm=2.5 * df, degree=3, eps=0.1, method, ...)
```

**Arguments**

<code>x</code>	predictor. The function does not apply to factor variables.
<code>df</code>	the desired degrees of freedom. One of the arguments <code>df</code> or <code>theta</code> must be given, but not both. If <code>df=0</code> , then the AIC = (loglik -df) is used to choose an "optimal" degrees of freedom. If AIC is chosen, then an optional argument <code>'caic=T'</code> can be used to specify the corrected AIC of Hurvich et. al.
<code>theta</code>	roughness penalty for the fit. It is a monotone function of the degrees of freedom, with <code>theta=1</code> corresponding to a linear fit and <code>theta=0</code> to an unconstrained fit of <code>nterm</code> degrees of freedom.
<code>nterm</code>	number of splines in the basis
<code>degree</code>	degree of splines
<code>eps</code>	accuracy for <code>df</code>
<code>method</code>	the method for choosing the tuning parameter <code>theta</code> . If <code>theta</code> is given, then <code>'fixed'</code> is assumed. If the degrees of freedom is given, then <code>'df'</code> is assumed. If <code>method='aic'</code> then the degrees of freedom is chosen automatically using Akaike's information criterion.
<code>...</code>	optional arguments to the control function

**Value**

Object of class `coxph.penalty` containing the spline basis, with the appropriate attributes to be recognized as a penalized term by the `coxph` or `survreg` functions.

**References**

Eilers, Paul H. and Marx, Brian D. (1996). Flexible smoothing with B-splines and penalties. *Statistical Science*, 11, 89-121.

pyears

*Person Years*

---

**Description**

This function computes the person-years of follow-up time contributed by a cohort of subjects, stratified into subgroups. It also computes the number of subjects who contribute to each cell of the output table, and optionally the number of events and/or expected number of events in each cell.

**Usage**

```
pyears(formula, data, weights, subset, na.action,
       ratetable=survexp.us, scale=365.25, expect=c('event', 'pyears'),
       model=FALSE, x=FALSE, y=FALSE, data.frame=FALSE)
```

**Arguments**

`formula` a formula object. The response variable will be a vector of follow-up times for each subject, or a `Surv` object containing the survival time and an event indicator. The predictors consist of optional grouping variables separated by `+` operators (exactly as in `survfit`), time-dependent grouping variables such as `age` (specified with `tcut`), and optionally a `ratetable` term. This latter matches each subject to his/her expected cohort.

<code>data</code>	a data frame in which to interpret the variables named in the <code>formula</code> , or in the <code>subset</code> and the <code>weights</code> argument.
<code>weights</code>	case weights.
<code>subset</code>	expression saying that only a subset of the rows of the data should be used in the fit.
<code>na.action</code>	a missing-data filter function, applied to the <code>model.frame</code> , after any <code>subset</code> argument has been used. Default is <code>options()\$na.action</code> .
<code>ratetable</code>	a table of event rates, such as <code>survexp.uswhite</code> .
<code>scale</code>	a scaling for the results. As most rate tables are in units/day, the default value of 365.25 causes the output to be reported in years.
<code>expect</code>	should the output table include the expected number of events, or the expected number of person-years of observation. This is only valid with a rate table.
<code>data.frame</code>	return a data frame rather than a set of arrays.
<code>model, x, y</code>	If any of these is true, then the model frame, the model matrix, and/or the vector of response times will be returned as components of the final result.

### Details

Because `pyears` may have several time variables, it is necessary that all of them be in the same units. For instance, in the call

```
py <- pyears(futime ~ rx + ratetable(age=age, sex=sex, year=entry.dt))
```

with a `ratetable` whose natural unit is days, it is important that `futime`, `age` and `entry.dt` all be in days. Given the wide range of possible inputs, it is difficult for the routine to do sanity checks of this aspect.

A special function `tcut` is needed to specify time-dependent cutpoints. For instance, assume that `age` is in years, and that the desired final arrays have as one of their margins the age groups 0-2, 2-10, 10-25, and 25+. A subject who enters the study at age 4 and remains under observation for 10 years will contribute follow-up time to both the 2-10 and 10-25 subsets. If `cut(age, c(0, 2, 10, 25, 100))` were used in the formula, the subject would be classified according to his starting age only. The `tcut` function has the same arguments as `cut`, but produces a different output object which allows the `pyears` function to correctly track the subject.

The results of `pyears` are normally used as input to further calculations. The `print` routine, therefore, is designed to give only a summary of the table.

The example below is from a study of hip fracture rates from 1930 - 1990 in Rochester, Minnesota. Survival post hip fracture has increased over that time, but so has the survival of elderly subjects in the population at large. A model of relative survival helps to clarify what has happened: Poisson regression is used, but replacing exposure time with expected exposure (for an age and sex matched control). Death rates change with age, of course, so the result is carved into 1 year increments of time. Males and females were done separately.

### Value

a list with components:

<code>pyears</code>	an array containing the person-years of exposure. (Or other units, depending on the rate table and the scale). The dimension and dimnames of the array correspond to the variables on the right hand side of the model equation.
---------------------	--

n	an array containing the number of subjects who contribute time to each cell of the <code>pyears</code> array.
event	an array containing the observed number of events. This will be present only if the response variable is a <code>Surv</code> object.
expected	an array containing the expected number of events (or person years if <code>expect="pyears"</code> ). This will be present only if there was a <code>ratetable</code> term.
data	if the <code>data.frame</code> option was set, a data frame containing the variables <code>n</code> , <code>event</code> , <code>pyears</code> and <code>event</code> that supplants the four arrays listed above, along with variables corresponding to each dimension. There will be one row for each cell in the arrays.
offtable	the number of person-years of exposure in the cohort that was not part of any cell in the <code>pyears</code> array. This is often useful as an error check; if there is a mismatch of units between two variables, nearly all the person years may be off table.
summary	a summary of the rate-table matching. This is also useful as an error check.
call	an image of the call to the function.
na.action	the <code>na.action</code> attribute contributed by an <code>na.action</code> routine, if any.

  ylab="Survival")
lines(efit, col=2, xscale=365.25) # Add the expected survival line

## End(Not run)
```

ratetables

*Census Data Sets for the Expected Survival and Person Years Functions***Description**

Census data sets for the expected survival and person years functions.

**Details**

**us** total United States population, by age and sex, 1960 to 1980.

**uswhite** United States white population, by age and sex, 1950 to 1980. This is no longer included, but can be extracted from `survexp.usr` as shown in the examples.

**usr** United States population, by age, sex and race, 1960 to 1980. Race is white, nonwhite, or black. For 1960 and 1970 the black population values were not reported separately, so the nonwhite values were used.

**mn** total Minnesota population, by age and sex, 1970 and 1980.

**mnwhite** Minnesota white population, by age and sex, 1960 to 1980.

**fl** total Florida population, by age and sex, 1970 and 1980.

**flr** Florida population, by age, sex and race, 1970-1980. Race is white, nonwhite, or black. For 1970 the black population values were not reported separately, so the nonwhite values were used.

**az** total Arizona population, by age and sex, 1970 and 1980.

**azr** Arizona population, by age, sex and race, 1970-1980. Race is white versus nonwhite. For 1970 the nonwhite population values were not reported separately. In order to make the rate table be a matrix, the 1980 values were repeated. (White and non-white values are quite different).

Each of these tables contains the daily hazard rate for a matched subject from the population, defined as  $-\log(1 - q)/365.24$  where  $q$  is the 1 year probability of death as reported in the original tables. For age 25 in 1970, for instance,  $p = 1 - q$  is the probability that a subject who becomes 25 years of age in 1970 will achieve his/her 26th birthday. The tables are recast in terms of hazard per day entirely for computational convenience. (The fraction .24 in the denominator is based on 24 leap years per century.)

Each table is stored as an array, with additional attributes, and can be subset and manipulated as standard S arrays. Interpolation between calendar years is done “on the fly” by the `survexp` routine.

Some of the deficiencies, e.g., 1970 Arizona non-white, are a result of local (Mayo Clinic) conditions. The data probably exists, but we don't have a copy it in the library.

The tables have been augmented to contain extrapolated values for 1990 and 2000. The details can be found in Mayo Clinic Biostatistics technical report 63 at <http://www.mayo.edu/hsr/techrpt.html>.

**Examples**

```
survexp.uswhite <- survexp.usr[,,"white",]
```

rats

*Rat data from Gail et al.***Description**

48 rats were injected with a carcinogen, and then randomized to either drug or placebo. The number of tumors ranges from 0 to 13; all rats were censored at 6 months after randomization.

**Usage**

rats

**Format**

rat:	id
rx:	treatment,(1=drug, 0=control)
observation:	within rat
start:	entry time
stop:	exit time
status:	event status

**Source**

residuals.coxph

*Calculate Residuals for a 'coxph' Fit***Description**

Calculates martingale, deviance, score or Schoenfeld residuals for a Cox proportional hazards model.

**Usage**

```
## S3 method for class 'coxph':
residuals(object,
  type=c("martingale", "deviance", "score", "schoenfeld",
        "dfbeta", "dfbetas", "scaledsch", "partial"),
  collapse=FALSE, weighted=FALSE, ...)
## S3 method for class 'coxph.null':
residuals(object,
  type=c("martingale", "deviance", "score", "schoenfeld"),
  collapse=FALSE, weighted=FALSE, ...)
```

**Arguments**

object	an object inheriting from class <code>coxph</code> , representing a fitted Cox regression model. Typically this is the output from the <code>coxph</code> function.
type	character string indicating the type of residual desired. Possible values are "martingale", "deviance", "score", "schoenfeld", "dfbeta", "dfbetas", and "scaledsch". Only enough of the string to determine a unique match is required.
collapse	vector indicating which rows to collapse (sum) over. In time-dependent models more than one row data can pertain to a single individual. If there were 4 individuals represented by 3, 1, 2 and 4 rows of data respectively, then <code>collapse=c(1,1,1, 2, 3,3, 4,4,4,4)</code> could be used to obtain per subject rather than per observation residuals.
weighted	if TRUE and the model was fit with case weights, then the weighted residuals are returned.
...	other unused arguments

**Value**

For martingale and deviance residuals, the returned object is a vector with one element for each subject (without `collapse`). For score residuals it is a matrix with one row per subject and one column per variable. The row order will match the input data for the original fit. For Schoenfeld residuals, the returned object is a matrix with one row for each event and one column per variable. The rows are ordered by time within strata, and an attribute `strata` is attached that contains the number of observations in each strata. The scaled Schoenfeld residuals are used in the `cox.zph` function.

The score residuals are each individual's contribution to the score vector. Two transformations of this are often more useful: `dfbeta` is the approximate change in the coefficient vector if that observation were dropped, and `dfbetas` is the approximate change in the coefficients, scaled by the standard error for the coefficients.

**NOTE**

For deviance residuals, the status variable may need to be reconstructed. For score and Schoenfeld residuals, the X matrix will need to be reconstructed.

**See Also**

[coxph](#)

**Examples**

```
fit <- coxph(Surv(start, stop, event) ~ (age + surgery)* transplant,
            data=heart)
mresid <- resid(fit, collapse=heart$id)
```

---

residuals.survreg *Compute Residuals for 'survreg' Objects*

---

## Description

This is a method for the function [residuals](#) for objects inheriting from class `survreg`.

## Usage

```
## S3 method for class 'survreg':
residuals(object, type=c("response", "deviance", "dfbeta", "dfbetas",
"working", "ldcase", "ldresp", "ldshape", "matrix"), rsigma=TRUE,
collapse=FALSE, weighted=FALSE, ...)
```

## Arguments

<code>object</code>	an object inheriting from class <code>survreg</code> .
<code>type</code>	type of residuals, with choices of "response", "deviance", "dfbeta", "dfbetas", "working", "ldcase", "lsresp", "ldshape", and "matrix". See the LaTeX documentation ( <a href="#">survival/doc/survival.ps.gz</a> ) for more detail.
<code>rsigma</code>	include the scale parameters in the variance matrix, when doing computations. (I can think of no good reason not to).
<code>collapse</code>	optional vector of subject groups. If given, this must be of the same length as the residuals, and causes the result to be per group residuals.
<code>weighted</code>	give weighted residuals? Normally residuals are unweighted.
<code>...</code>	other unused arguments

## Value

A vector or matrix of residuals is returned. Response residuals are on the scale of the original data, working residuals are on the scale of the linear predictor, and deviance residuals are on log-likelihood scale. The `dfbeta` residuals are a matrix, where the *i*th row gives the approximate change in the coefficients due to the addition of subject *i*. The `dfbetas` matrix contains the `dfbeta` residuals, with each column scaled by the standard deviation of that coefficient.

The `matrix` type produces a matrix based on derivatives of the log-likelihood function. Let  $L$  be the log-likelihood,  $p$  be the linear predictor  $X\beta$ , and  $s$  be  $\log(\sigma)$ . Then the 6 columns of the matrix are  $L$ ,  $dL/dp$ ,  $\partial^2 L/\partial p^2$ ,  $dL/ds$ ,  $\partial^2 L/\partial s^2$  and  $\partial^2 L/\partial p \partial s$ . Diagnostics based on these quantities are discussed in an article by Escobar and Meeker. The main ones are the likelihood displacement residuals for perturbation of a case weight (`ldcase`), the response value (`ldresp`), and the shape.

rr <- residuals(fit, type='matrix')
```

---

 ridge

*Ridge regression*

---

**Description**

When used in a [coxph](#) or [survreg](#) model formula, specifies a ridge regression term. The likelihood is penalised by  $\theta/2$  time the sum of squared coefficients. If `scale=T` the penalty is calculated for coefficients based on rescaling the predictors to have unit variance. If `df` is specified then  $\theta$  is chosen based on an approximate degrees of freedom.

**Usage**

```
ridge(..., theta, df=nvar/2, eps=0.1, scale=TRUE)
```

**Arguments**

<code>...</code>	predictors to be ridged
<code>theta</code>	penalty is $\theta/2$ time sum of squared coefficients
<code>df</code>	Approximate degrees of freedom
<code>eps</code>	Accuracy required for <code>df</code>
<code>scale</code>	Scale variables before applying penalty?

**Value**

An object of class `coxph.penalty` containing the data and control functions.

[predict.survreg](#), [heart](#)

---

`strata`*Identify Stratification Variables*

---

**Description**

This is a special function used in the context of the Cox survival model. It identifies stratification variables when they appear on the right hand side of a formula.

**Usage**

```
strata(..., na.group=FALSE, shortlabel=FALSE, sep=', ')
```

**Arguments**

<code>...</code>	any number of variables. All must be the same length.
<code>na.group</code>	a logical variable, if TRUE, then missing values are treated as a distinct level of each variable.
<code>shortlabel</code>	if TRUE omit variable names from resulting factor labels
<code>sep</code>	the character used to separate groups, in the created label

**Details**

The result is identical to the `interaction` function, but for the labeling of the factors (`strata` is more verbose).

**Value**

a new factor, whose levels are all possible combinations of the factors supplied as arguments.

**See Also**

[coxph](#), [interaction](#)

**Examples**

```
a<-factor(rep(1:3,4))
b<-factor(rep(1:4,3))
levels(strata(a))
levels(strata(a,b,shortlabel=TRUE))

coxph(Surv(futime, fustat) ~ age + strata(rx), data=ovarian)
```

---

summary.aareg

*Summarize an aareg fit*

---

**Description**

Creates the overall test statistics for an Aalen additive regression model

**Usage**

```
## S3 method for class 'aareg':
summary(object, maxtime, test=c("aalen", "nrisk"), scale=1,...)
```

**Arguments**

<code>object</code>	the result of a call to the <code>aareg</code> function
<code>maxtime</code>	truncate the input to the model at time "maxtime"
<code>test</code>	the relative time weights that will be used to compute the test
<code>scale</code>	scales the coefficients. For some data sets, the coefficients of the Aalen model will be very small (10 <sup>-4</sup> ); this simply multiplies the printed values by a constant, say 1e6, to make the printout easier to read.
<code>...</code>	for future methods

**Details**

It is not uncommon for the very right-hand tail of the plot to have large outlying values, particularly for the standard error. The `maxtime` parameter can then be used to truncate the range so as to avoid these. This gives an updated value for the test statistics, without refitting the model.

**Value**

a list is returned with the following components

<code>table</code>	a matrix with rows for the intercept and each covariate, and columns giving a slope estimate, the test statistic, its standard error, the z-score and a p-value
<code>test</code>	the time weighting used for computing the test statistics
<code>test.statistic</code>	the vector of test statistics
<code>test.var</code>	the model based variance matrix for the test statistic
<code>test.var2</code>	optionally, a robust variance matrix for the test statistic
<code>chisq</code>	the overall test (ignoring the intercept term) for significance of any variable
<code>n</code>	a vector containing the number of observations, the number of unique death times used in the computation, and the total number of unique death times

**See Also**

`aareg`, `plot.aareg`

**Examples**

```

## End(Not run)
```

---

summary.survfit      *Summary of a Survival Curve*

---

### Description

Returns a list containing the survival curve, confidence limits for the curve, and other information.

### Usage

```
## S3 method for class 'survfit':
summary(object, times=, censored=FALSE, scale=1,
        extend=FALSE, rmean=getOption('survfit.rmean'), ...)
```

### Arguments

object	the result of a call to the <code>survfit</code> function.
times	vector of times; the returned matrix will contain 1 row for each time. This must be in increasing order and missing values are not allowed. If <code>censored=T</code> , the default <code>times</code> vector contains all the unique times in <code>fit</code> , otherwise the default <code>times</code> vector uses only the event (death) times.
censored	logical value: should the censoring times be included in the output? This is ignored if the <code>times</code> argument is present.
scale	numeric value to rescale the survival time, e.g., if the input data to <code>survfit</code> were in days, <code>scale = 365.25</code> would scale the output to years.
extend	logical value: if TRUE, prints information for all specified <code>times</code> , even if there are no subjects left at the end of the specified <code>times</code> . This is only valid if the <code>times</code> argument is present.
rmean	Show restricted mean: see <a href="#">print.summary.survfit</a> for details
...	for future methods

### Value

a list with the following components:

surv	the estimate of survival at time $t+0$ .
time	the timepoints on the curve.
n.risk	the number of subjects at risk at time $t-0$ (but see the comments on weights in the <code>survfit</code> help file).
n.event	if the <code>times</code> argument is missing, then this column is the number of events that occurred at time $t$ . Otherwise, it is the cumulative number of events that have occurred since the last time listed until time $t+0$ .
n.entered	This is present only for counting process survival data. If the <code>times</code> argument is missing, this column is the number of subjects that entered at time $t$ . Otherwise, it is the cumulative number of subjects that have entered since the last time listed until time $t$ .

<code>n.exit.censored</code>	if the <code>times</code> argument is missing, this column is the number of subjects that left without an event at time <code>t</code> . Otherwise, it is the cumulative number of subjects that have left without an event since the last time listed until time <code>t+0</code> . This is only present for counting process survival data.
<code>std.err</code>	the standard error of the survival value.
<code>conf.int</code>	level of confidence for the confidence intervals of survival.
<code>lower</code>	lower confidence limits for the curve.
<code>upper</code>	upper confidence limits for the curve.
<code>strata</code>	indicates stratification of curve estimation. If <code>strata</code> is not <code>NULL</code> , there are multiple curves in the result and the <code>surv</code> , <code>time</code> , <code>n.risk</code> , etc. vectors will contain multiple curves, pasted end to end. The levels of <code>strata</code> (a factor) are the labels for the curves.
<code>call</code>	the statement used to create the <code>fit</code> object.
<code>na.action</code>	same as for <code>fit</code> , if present.
<code>table</code>	table of information that is returned from <code>print.survfit</code> function.
<code>type</code>	type of data censoring. Passed through from the <code>fit</code> object.

Surv

*Create a Survival Object***Description**

Create a survival object, usually used as a response variable in a model formula. Argument matching is special for this function, see Details below.

**Usage**

```
Surv(time, time2, event,
      type=c('right', 'left', 'interval', 'counting', 'interval2'),
      origin=0)
is.Surv(x)
```

**Arguments**

`time` for right censored data, this is the follow up time. For interval data, the first argument is the starting time for the interval.

event	The status indicator, normally 0=alive, 1=dead. Other choices are TRUE/FALSE (TRUE = death) or 1/2 (2=death). For interval censored data, the status indicator is 0=right censored, 1=event at time, 2=left censored, 3=interval censored. Although unusual, the event indicator can be omitted, in which case all subjects are assumed to have an event.
time2	ending time of the interval for interval censored or counting process data only. Intervals are assumed to be open on the left and closed on the right, (start, end]. For counting process data, event indicates whether an event occurred at the end of the interval.
type	character string specifying the type of censoring. Possible values are "right", "left", "counting", "interval", or "interval2". The default is "right" or "counting" depending on whether the time2 argument is absent or present, respectively.
origin	for counting process data, the hazard function origin. This option was intended to be used in conjunction with a model containing time dependent strata in order to align the subjects properly when they cross over from one strata to another, but it has rarely proven useful.
x	any R object.

## Details

Typical usages are

```
Surv(time, event)
Surv(time, time2, event, type= )
```

The time,time2 and event arguments are matched by position, not by name, so use, eg, Surv(time, dead) rather than Surv(time, event=dead)

In theory it is possible to represent interval censored data without a third column containing the explicit status. Exact, right censored, left censored and interval censored observation would be represented as intervals of [a,a], (a, infinity), (-infinity,b), and [a,b] respectively; each interval is a pair of time points within which the event is known to have occurred.

If type="interval2" then the representation given above is assumed, with NA taking the place of infinity. If type="interval" then event must be given. If event is 0, 1, or 2, the relevant information is assumed to be contained in time, the value in time2 is ignored, and the second column of the internal representation contains a placeholder value.

Presently, the only methods allowing interval censored data are the parametric models computed by survreg and survival curves computed by survfit; for both of these, the distinction between open and closed intervals is unimportant. The distinction is important for counting process data and the Cox model.

The function tries to distinguish between the use of 0/1 and 1/2 coding for left and right censored data using if (max(status)==2). If 1/2 coding is used and all the subjects are censored, it will guess wrong. In any questionable case it is safer to use logical coding, e.g., Surv(time, status==3) would indicate that a 3 is the code for an event.

Surv objects can be subscripted either as an object, e.g. x[1:3] using a single subscript; in which case the drop argument is ignored; or as a matrix, using two arguments. If the second subscript is missing and drop=F (the default), the result of the subscripting will be a Surv object, e.g., x[1:3, , drop=F], otherwise the result will be a matrix (or vector), in accordance with the default behavior for subscripting matrices.

**Value**

An object of class `Surv`. There are methods for `print`, `is.na`, and subscripting survival objects. `Surv` objects are implemented as a matrix of 2 or 3 columns.

In the case of `is.Surv`, a logical value `TRUE` if `x` inherits from class `"Surv"`, otherwise an `FALSE`.

**See Also**

`coxph`, `survfit`, `survreg`.

**Examples**

```
with(lung, Surv(time, status))
Surv(heart$start, heart$stop, heart$event)
```

---

`survConcordance`      *Compute a concordance measure.*

---

**Description**

This function computes the concordance between a right-censored survival time and a single continuous covariate

**Usage**

```
survConcordance(formula, data, weights, subset, na.action)
```

**Arguments**

`formula`            a formula with a survival time on the left and a single covariate on the right.  
`data`                a data frame  
`weights, subset, na.action`  
                      as for `coxph`

**Details**

Concordance is defined as  $\Pr(\text{agreement})$  for any two randomly chosen observations, where in this case agreement means that the observation with the shorter survival time of the two also has the larger risk score. The predictor (or risk score) will often be the result of a Cox model or other regression.

For continuous covariates concordance is equivalent to Kendall's tau, and for logistic regression is equivalent to the area under the ROC curve. A value of 1 signifies perfect agreement, .6-.7 a common result for survival data, .5 an agreement that is no better than chance, and .3-.4 the performance of some stock market analysts.

The computation involves all  $n(n-1)/2$  pairs of data points in the sample. For survival data, however, some of the pairs are incomparable. For instance a pair of times (5+, 8), the first being a censored value. We do not know whether the first survival time is greater than or less than the second. Among observations that are comparable, pairs may also be tied on survival time (but only if both are uncensored) or on the predictor. The final concordance is  $(\text{agree} + \text{tied}/2)/(\text{agree} + \text{disagree} + \text{tied})$ .

There is, unfortunately, one aspect of the formula above that is unclear. Should the count of ties include observations that are tied on survival time  $y$ , tied on the predictor  $x$ , or both? In 2 by 2 tables, Kendall's tau-b is equal to  $(\text{agree} - \text{disagree})/n$ , where  $n$  is the geometric mean of  $(\text{agree} + \text{disagree} + \text{tied.x})$  and  $(\text{agree} + \text{disagree} + \text{tied.y})$ . The Goodman-Kruskal Gamma statistic is  $(\text{agree} - \text{disagree})/(\text{agree} + \text{disagree})$ , ignoring ties. It ranges from -1 to +1 similar to a correlation coefficient.

In this program we count those observations which were tied on  $x$ , but not tied on  $y$  (survival time), as 'ties'. All of the components are returned in the result, however, so people can compute other combinations if interested. (If two observations have the same survival and the same  $x$ , they are counted in the tied.time category).

### Value

an object containing the concordance, followed by the number of pairs that agree, disagree, are tied, and are not comparable.

### See Also

summary.coxph

## End(Not run)
```

---

survdiff

*Test Survival Curve Differences*

---

### Description

Tests if there is a difference between two or more survival curves using the  $G^p$  family of tests, or for a single curve against a known alternative.

### Usage

```
survdiff(formula, data, subset, na.action, rho=0)
```

**Arguments**

<code>formula</code>	a formula expression as for other survival models, of the form <code>Surv(time, status) ~ predictors</code> . For a one-sample test, the predictors must consist of a single <code>offset(sp)</code> term, where <code>sp</code> is a vector giving the survival probability of each subject. For a k-sample test, each unique combination of predictors defines a subgroup. A <code>strata</code> term may be used to produce a stratified test. To cause missing values in the predictors to be treated as a separate group, rather than being omitted, use the <code>strata</code> function with its <code>na.group=T</code> argument.
<code>data</code>	an optional data frame in which to interpret the variables occurring in the formula.
<code>subset</code>	expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector (which is replicated to have length equal to the number of observations), a numeric vector indicating which observation numbers are to be included (or excluded if negative), or a character vector of row names to be included. All observations are included by default.
<code>na.action</code>	a missing-data filter function. This is applied to the <code>model.frame</code> after any subset argument has been used. Default is <code>options()\$na.action</code> .
<code>rho</code>	a scalar parameter that controls the type of test.

**Value**

a list with components:

<code>n</code>	the number of subjects in each group.
<code>obs</code>	the weighted observed number of events in each group. If there are strata, this will be a matrix with one column per stratum.
<code>exp</code>	the weighted expected number of events in each group. If there are strata, this will be a matrix with one column per stratum.
<code>chisq</code>	the chisquare statistic for a test of equality.
<code>var</code>	the variance matrix of the test.
<code>strata</code>	optionally, the number of subjects contained in each stratum.

**METHOD**

This function implements the G-rho family of Harrington and Fleming (1982), with weights on each death of  $S(t)^\rho$ , where  $S(t)$  is the Kaplan-Meier estimate of survival. With `rho = 0` this is the log-rank or Mantel-Haenszel test, and with `rho = 1` it is equivalent to the Peto & Peto modification of the Gehan-Wilcoxon test.

If the right hand side of the formula consists only of an offset term, then a one sample test is done. To cause missing values in the predictors to be treated as a separate group, rather than being omitted, use the `factor` function with its `exclude` argument.

**References**

Harrington, D. P. and Fleming, T. R. (1982). A class of rank test procedures for censored survival data. *Biometrika* **69**, 553-566.

**Examples**

```
## Two-sample test
survdif(Surv(futime, fustat) ~ rx, data=ovarian)

## Stratified 7-sample test

survdif(Surv(time, status) ~ pat.karno + strata(inst), data=lung)

## Expected survival for heart transplant patients based on
## US mortality tables
expect <- survexp(futime ~ ratetable(age=(accept.dt - birth.dt),
  sex=1, year=accept.dt, race="white"), jasa, cohort=FALSE,
  ratetable=survexp.usr)
## actual survival is much worse (no surprise)
survdif(Surv(jasa$futime, jasa$fustat) ~ offset(expect))
```

survexp

*Compute Expected Survival***Description**

Returns either the expected survival of a cohort of subjects, or the individual expected survival for each subject.

**Usage**

```
survexp(formula, data, weights, subset, na.action, times, cohort=TRUE,
  conditional=FALSE, ratetable=survexp.us, scale=1, npoints,
  se.fit, model=FALSE, x=FALSE, y=FALSE)
```

**Arguments**

formula	formula object. The response variable is a vector of follow-up times and is optional. The predictors consist of optional grouping variables separated by the + operator (as in <code>survfit</code> ), along with a <code>ratetable</code> term. The <code>ratetable</code> term matches each subject to his/her expected cohort.
data	data frame in which to interpret the variables named in the <code>formula</code> , <code>subset</code> and <code>weights</code> arguments.
weights	case weights.
subset	expression indicating a subset of the rows of <code>data</code> to be used in the fit.
na.action	function to filter missing data. This is applied to the model frame after <code>subset</code> has been applied. Default is <code>options()\$na.action</code> . A possible value for <code>na.action</code> is <code>na.omit</code> , which deletes observations that contain one or more missing values.
times	vector of follow-up times at which the resulting survival curve is evaluated. If absent, the result will be reported for each unique value of the vector of follow-up times supplied in <code>formula</code> .
cohort	logical value: if <code>FALSE</code> , each subject is treated as a subgroup of size 1. The default is <code>TRUE</code> .

<code>conditional</code>	logical value: if TRUE, the follow-up times supplied in <code>formula</code> are death times and conditional expected survival is computed. If FALSE, the follow-up times are potential censoring times. If follow-up times are missing in <code>formula</code> , this argument is ignored.
<code>ratetable</code>	a table of event rates, such as <code>survexp.uswhite</code> , or a fitted Cox model.
<code>scale</code>	numeric value to scale the results. If <code>ratetable</code> is in units/day, <code>scale = 365.25</code> causes the output to be reported in years.
<code>npoints</code>	number of points at which to calculate intermediate results, evenly spaced over the range of the follow-up times. The usual (exact) calculation is done at each unique follow-up time. For very large data sets specifying <code>npoints</code> can reduce the amount of memory and computation required. For a prediction from a Cox model <code>npoints</code> is ignored.
<code>se.fit</code>	compute the standard error of the predicted survival. The default is to compute standard errors whenever possible, which at this time is only for the Ederer method and a Cox model as the rate table.
<code>model, x, y</code>	flags to control what is returned. If any of these is true, then the model frame, the model matrix, and/or the vector of response times will be returned as components of the final result, with the same names as the flag arguments.

## Details

Individual expected survival is usually used in models or testing, to ‘correct’ for the age and sex composition of a group of subjects. For instance, assume that birth date, entry date into the study, sex and actual survival time are all known for a group of subjects. The `survexp.uswhite` population tables contain expected death rates based on calendar year, sex and age. Then

```
haz <- -log(survexp(death.time ~ ratetable(sex=sex, year=entry.dt,
                                         age=(birth.dt-entry.dt)), cohort=FALSE))
```

gives for each subject the total hazard experienced up to their observed death time or censoring time. This probability can be used as a rescaled time value in models:

```
glm(status ~ 1 + offset(log(haz)), family=poisson)
glm(status ~ x + offset(log(haz)), family=poisson)
```

In the first model, a test for `intercept=0` is the one sample log-rank test of whether the observed group of subjects has equivalent survival to the baseline population. The second model tests for an effect of variable `x` after adjustment for age and sex.

Cohort survival is used to produce an overall survival curve. This is then added to the Kaplan-Meier plot of the study group for visual comparison between these subjects and the population at large. There are three common methods of computing cohort survival. In the "exact method" of Ederer the cohort is not censored; this corresponds to having no response variable in the formula. Hakulinen recommends censoring the cohort at the anticipated censoring time of each patient, and Verheul recommends censoring the cohort at the actual observation time of each patient. The last of these is the conditional method. These are obtained by using the respective time values as the follow-up time or response in the formula.

## Value

if `cohort=TRUE` an object of class `survexp`, otherwise a vector of per-subject expected survival values. The former contains the number of subjects at risk and the expected survival for the cohort at each requested time.

lines(survexp(~ trt, ratetable=pfit, data=pbcc), col='purple')
```

---

survexp.fit

*Compute Expected Survival*

---

## Description

Compute expected survival times.

## Usage

```
survexp.fit(x, y, times, death, ratetable)
```

## Arguments

- |           |   |
|-----------|---|
| x         | a matrix. The first column contains the group, an integer value that divides the subjects into subsets. Remaining columns must match the dimensions of the ratetable, in the correct order. |
| y         | the follow up time for each subject.  |
| times     | the vector of times at which a result will be computed.   |
| death     | a logical value, if TRUE the conditional survival is computed, if FALSE the cohort survival is computed. See <a href="#">survexp</a> for more details.                                      |
| ratetable | a rate table, such as <a href="#">survexp.uswhite</a> .   |

**Details**

For conditional survival  $y$  must be the time of last follow-up or death for each subject. For cohort survival it must be the potential censoring time for each subject, ignoring death.

For an exact estimate `times` should be a superset of  $y$ , so that each subject at risk is at risk for the entire sub-interval of time. For a large data set, however, this can use an inordinate amount of storage and/or compute time. If the `times` spacing is more coarse than this, an actuarial approximation is used which should, however, be extremely accurate as long as all of the returned values are  $> .99$ .

For a subgroup of size 1 and `times`  $> y$ , the conditional method reduces to  $\exp(-h)$  where  $h$  is the expected cumulative hazard for the subject over his/her observation time. This is used to compute individual expected survival.

**Value**

A list containing the number of subjects and the expected survival(s) at each time point. If there are multiple groups, these will be matrices with one column per group.

**Warning**

Most users will call the higher level routine `survexp`. Consequently, this function has very few error checks on its input arguments.

**See Also**

[survexp](#), [survexp.us](#).

---

survfit

*Create survival curves*

---

**Description**

This function creates survival curves from either a formula (e.g. the Kaplan-Meier), a previously fitted Cox model, or a previously fitted accelerated failure time model.

**Usage**

```
survfit(formula, ...)
```

**Arguments**

<code>formula</code>	either a formula or a previously fitted model
<code>...</code>	other arguments to the specific method

**Details**

For details see the documentation for the appropriate method, i.e., `?survfit.formula` or `?survfit.coxph`.

**Value**

An object of class `survfit` containing one or more survival curves.

**Note**

Older releases of the code also allowed the specification for a single curve to omit the right hand of the formula, i.e.,  $\sim 1$ . Handling this case required some non-standard and fairly fragile manipulations, and this case is no longer supported.

**Author(s)**

Terry Therneau

`plot.survfit`, `summary.survfit`

---

`survfit.coxph`

*Compute a Survival Curve from a Cox model*

---

**Description**

Computes the predicted survivor function for a Cox proportional hazards model.

**Usage**

```
## S3 method for class 'coxph':
survfit(formula, newdata,
        se.fit=TRUE, conf.int=.95,
        individual=FALSE,
        type, vartype,
        conf.type=c("log", "log-log", "plain", "none"), ...)
```

**Arguments**

<code>formula</code>	A <code>coxph</code> object.
<code>newdata</code>	a data frame with the same variable names as those that appear in the <code>coxph</code> formula. The curve(s) produced will be representative of a cohort whose covariates correspond to the values in <code>newdata</code> . Default is the mean of the covariates used in the <code>coxph</code> fit.
<code>individual</code>	a logical value indicating whether each row of <code>newdata</code> represents a distinct individual (FALSE, the default), or if each row of the data frame represents different time epochs for only one individual (TRUE). In the former case the result will have one curve for each row in <code>newdata</code> , in the latter only a single curve will be produced.
<code>conf.int</code>	the level for a two-sided confidence interval on the survival curve(s). Default is 0.95.
<code>se.fit</code>	a logical value indicating whether standard errors should be computed. Default is TRUE.

<code>type, vartype</code>	a character string specifying the type of survival curve. Possible values are "aalen" or "kaplan-meier" (only the first two characters are necessary). The default is "aalen". Earlier versions of <code>survfit</code> used <code>type="tsiatis"</code> to get the "aalen" estimator. For backward compatibility, this is still allowed.
<code>conf.type</code>	One of "none", "plain", "log" (the default), or "log-log". Only enough of the string to uniquely identify it is necessary. The first option causes confidence intervals not to be generated. The second causes the standard intervals $\text{curve} \pm k * \text{se}(\text{curve})$ , where $k$ is determined from <code>conf.int</code> . The log option calculates intervals based on the cumulative hazard or $\log(\text{survival})$ . The last option bases intervals on the log hazard or $\log(-\log(\text{survival}))$ .
<code>...</code>	for future methods

### Details

See [survfit](#) for more Details.

The estimates used are the Kalbfleisch-Prentice (Kalbfleisch and Prentice, 1980, p.86) and the Tsiatis/Link/Breslow, which reduce to the Kaplan-Meier and Fleming-Harrington estimates, respectively, when the weights are unity. When the parent data is a Cox model, there is an extra term in the variance of the curve, due to the variance of the coefficients and hence variance in the computed weights. Details of the Aalen estimator and its variance are found in Tsiatis (1981).

The two variants of the F-H estimate have to do with how ties are handled. If there were 3 deaths out of 10 at risk, then the first increments the hazard by  $3/10$  and the second by  $1/10 + 1/9 + 1/8$ . For the first method  $S(t) = \exp(H)$ , where  $H$  is the Nelson-Aalen cumulative hazard estimate, whereas the `fh2` method will give results  $S(t)$  results closer to the Kaplan-Meier. For curves created after a Cox model these correspond to the Breslow and Efron estimates, respectively, and the proper choice is made automatically.

### Value

an object of class "survfit". See `survfit.object` for details. Methods defined for `survfit` objects are `print`, `plot`, `lines`, and `points`.

survfit.formula

*Compute a Survival Curve for Censored Data***Description**

Computes an estimate of a survival curve for censored data using either the Kaplan-Meier or the Fleming-Harrington method. For competing risks data it computes the cumulative incidence curve.

**Usage**

```
## S3 method for class 'formula':
survfit(formula, data, weights, subset, na.action,
        etype, id, ...)
```

**Arguments**

- |           |  |
|-----------|--|
| formula   | a formula object, which must have a <code>Surv</code> object as the response on the left of the <code>~</code> operator and, if desired, terms separated by <code>+</code> operators on the right. One of the terms may be a <code>strata</code> object. For a single survival curve the right hand side should be <code>~ 1</code> .  |
| data      | a data frame in which to interpret the variables named in the formula, <code>subset</code> and <code>weights</code> arguments.   |
| weights   | The weights must be nonnegative and it is strongly recommended that they be strictly positive, since zero weights are ambiguous, compared to use of the <code>subset</code> argument.  |
| subset    | expression saying that only a subset of the rows of the data should be used in the fit.  |
| na.action | a missing-data filter function, applied to the model frame, after any <code>subset</code> argument has been used. Default is <code>options()\$na.action</code> .   |
| etype     | a variable giving the type of event. Presence of this variable signals the program to compute the cumulative incidence estimate. For each event <code>status==1</code> , the <code>etype</code> variable indicates the type of event. For a censored observation the value of <code>etype</code> is ignored - but do not set it to <code>NA</code> , since that will cause <code>na.action</code> to delete the observation.   |
| id        | identifies individual subjects, when a given person can have multiple lines of data. when used with the <code>etype</code> variable, this allows the computation of a cumulative prevalence estimate, i.e., the incidence over time.   |
| ...       | The following additional arguments are passed to internal functions called by <code>survfit</code> .<br><b>type</b> a character string specifying the type of survival curve. Possible values are "kaplan-meier", "fleming-harrington" or "fh2" if a formula is given. This is ignored for competing risks or when the Turnbull estimator is used.<br><b>error</b> a character string specifying the error. Possible values are "greenwood" for the Greenwood formula or "tsiatis" for the Tsiatis formula, (only the first character is necessary).<br><b>conf.type</b> One of "none", "plain", "log" (the default), or "log-log". Only enough of the string to uniquely identify it is necessary. The first option causes confidence intervals not to be generated. The second causes the standard intervals $curve \pm k * se(curve)$ , where <code>k</code> is determined from <code>conf.int</code> . The <code>log</code> option calculates intervals based on the cumulative hazard or $\log(\text{survival})$ . The last option bases intervals on the log hazard or $\log(-\log(\text{survival}))$ .<br><b>conf.lower</b> a character string to specify modified lower limits to the curve, the upper limit remains unchanged. Possible values are "usual" (unmodified), "peto", and "modified". The modified lower limit is based on an "effective n" argument. The confidence bands will agree with the usual calculation at each death time, but unlike the usual bands the confidence |

interval becomes wider at each censored observation. The extra width is obtained by multiplying the usual variance by a factor  $m/n$ , where  $n$  is the number currently at risk and  $m$  is the number at risk at the last death time. (The bands thus agree with the un-modified bands at each death time.) This is especially useful for survival curves with a long flat tail.

The Peto lower limit is based on the same "effective  $n$ " argument as the modified limit, but also replaces the usual Greenwood variance term with a simple approximation. It is known to be conservative.

**start.time** numeric value specifying a time to start calculating survival information. The resulting curve is the survival conditional on surviving to `start.time`.

**conf.int** the level for a two-sided confidence interval on the survival curve(s). Default is 0.95.

**se.fit** a logical value indicating whether standard errors should be computed. Default is TRUE.

## Details

The estimates used are the Kalbfleisch-Prentice (Kalbfleisch and Prentice, 1980, p.86) and the Tsiatis/Link/Breslow, which reduce to the Kaplan-Meier and Fleming-Harrington estimates, respectively, when the weights are unity.

The Greenwood formula for the variance is a sum of terms  $d/(n*(n-m))$ , where  $d$  is the number of deaths at a given time point,  $n$  is the sum of weights for all individuals still at risk at that time, and  $m$  is the sum of weights for the deaths at that time. The justification is based on a binomial argument when weights are all equal to one; extension to the weighted case is ad hoc. Tsiatis (1981) proposes a sum of terms  $d/(n*n)$ , based on a counting process argument which includes the weighted case.

The two variants of the F-H estimate have to do with how ties are handled. If there were 3 deaths out of 10 at risk, then the first increments the hazard by  $3/10$  and the second by  $1/10 + 1/9 + 1/8$ . For the first method  $S(t) = \exp(H)$ , where  $H$  is the Nelson-Aalen cumulative hazard estimate, whereas the `fn2` method will give results  $S(t)$  results closer to the Kaplan-Meier.

When the data set includes left censored or interval censored data (or both), then the EM approach of Turnbull is used to compute the overall curve. When the baseline method is the Kaplan-Meier, this is known to converge to the maximum likelihood estimate.

The cumulative incidence curve is an alternative to the Kaplan-Meier for competing risks data. For instance, in patients with MGUS, conversion to an overt plasma cell malignancy occurs at a nearly constant rate among those still alive. A Kaplan-Meier estimate, treating death due to other causes as censored, gives a 20 year cumulative rate of 33% for the 241 early patients of Kyle. This estimates the incidence of conversion, if other causes of death were removed.

The CI estimate, on the other hand, estimates the total number of conversions that will actually occur. Because the population is older, this is much smaller than the KM, 22% at 20 years for Kyle's data. If there were no censoring, then  $CI(t)$  could very simply be computed as total number of patients with progression by time  $t$  divided by the sample size  $n$ .

## Value

an object of class "survfit". See `survfit.object` for details. Methods defined for `survfit` objects are `print`, `plot`, `lines`, and `points`.

---

survfit.object      *Survival Curve Object*

---

## Description

This class of objects is returned by the `survfit` class of functions to represent a fitted survival curve.

Objects of this class have methods for the functions `print`, `summary`, `plot`, `points` and `lines`. The `print.survfit` method does more computation than is typical for a print method and is documented on a separate page. Class of objects that represent a fitted survival curve.

## Arguments

<code>n</code>	total number of subjects in each curve.
<code>time</code>	the time points at which the curve has a step.
<code>n.risk</code>	the number of subjects at risk at <code>t</code> .
<code>n.event</code>	the number of events that occur at time <code>t</code> .
<code>n.enter</code>	for counting process data only, the number of subjects that enter at time <code>t</code> .
<code>n.censor</code>	for counting process data only, the number of subjects who exit the risk set, without an event, at time <code>t</code> . (For right censored data, this number can be computed from the successive values of the number at risk).
<code>surv</code>	the estimate of survival at time <code>t+0</code> . This may be a vector or a matrix.
<code>std.err</code>	the standard error of the cumulative hazard or $-\log(\text{survival})$ .
<code>upper</code>	upper confidence limit for the survival curve.
<code>lower</code>	lower confidence limit for the survival curve.
<code>strata</code>	if there are multiple curves, this component gives the number of elements of the <code>time</code> etc. vectors corresponding to the first curve, the second curve, and so on. The names of the elements are labels for the curves.
<code>start.time</code>	the value specified for the <code>start.time</code> argument, if it was used in the call.
<code>n.all</code>	for counting process data, and any time that the <code>start.time</code> argument was used, this contains the total number of observations that were available. Not all may have been used in creating the curve, in which case this value will be larger than <code>n</code> above. of observations that were available
<code>conf.type</code>	the approximation used to compute the confidence limits.
<code>conf.int</code>	the level of the confidence limits, e.g. 90 or 95%.
<code>na.action</code>	the returned value from the <code>na.action</code> function, if any. It will be used in the printout of the curve, e.g., the number of observations deleted due to missing values.
<code>call</code>	an image of the call that produced the object.
<code>type</code>	type of survival censoring.

**Structure**

The following components must be included in a legitimate `survfit` object.

**Subscripts**

Survfit objects that contain multiple survival curves can be subscripted. This is most often used to plot a subset of the curves. Usually a single subscript will be used. In one particular case – survival curves for multiple covariate values, from a Cox model that includes a `strata` statement – there is a matrix of curves and 2 subscripts may be used. (In this case `summary.survfit` will also print the data as a matrix).

---

survobrien

*O'Brien's Test for Association of a Single Variable with Survival*

---

**Description**

Peter O'Brien's test for association of a single variable with survival This test is proposed in Biometrics, June 1978.

**Usage**

```
survobrien(formula, data)
```

**Arguments**

<code>formula</code>	a valid formula for a cox model, without time dependent covariates.
<code>data</code>	a data frame.

**Value**

a new data frame. The original time and status variables are removed, and have been replaced with `start`, `stop`, and `event`. If a predictor variable is a factor or is protected with `I()`, it is retained as is. Other predictor variables have been replaced with time-dependent logit scores.

Because of the time dependent variables, the new data frame will have many more rows than the original data, approximately  $\#rows * \#deaths / 2$ .

**Method**

A time-dependent cox model can now be fit to the new data. The univariate statistic, as originally proposed, is equivalent to single variable score tests from the time-dependent model. This equivalence is the rationale for using the time dependent model as a multivariate extension of the original paper.

In O'Brien's method, the x variables are re-ranked at each death time. A simpler method, proposed by Prentice, ranks the data only once at the start. The results are usually similar.

coxph(Surv(start, stop, event) ~ age + rx + ecog.ps, data=xx)
```

---

survreg

*Regression for a Parametric Survival Model*

---

## Description

Fit a parametric survival regression model. These are location-scale models for an arbitrary transform of the time variable; the most common cases use a log transformation, leading to accelerated failure time models.

## Usage

```
survreg(formula, data, weights, subset,
  na.action, dist="weibull", init=NULL, scale=0,
  control, parms=NULL, model=FALSE, x=FALSE,
  y=TRUE, robust=FALSE, score=FALSE, ...)
```

## Arguments

formula	a formula expression as for other regression models. The response is usually a survival object as returned by the <code>Surv</code> function. See the documentation for <code>Surv</code> , <code>lm</code> and <code>formula</code> for details.
data	a data frame in which to interpret the variables named in the <code>formula</code> , <code>weights</code> or the <code>subset</code> arguments.
weights	optional vector of case weights
subset	subset of the observations to be used in the fit
na.action	a missing-data filter function, applied to the <code>model.frame</code> , after any <code>subset</code> argument has been used. Default is <code>options()\$na.action</code> .
dist	assumed distribution for <code>y</code> variable. If the argument is a character string, then it is assumed to name an element from <code>survreg.distributions</code> . These include "weibull", "exponential", "gaussian", "logistic", "lognormal" and "loglogistic". Otherwise, it is assumed to be a user defined list conforming to the format described in <code>survreg.distributions</code> .

parms	a list of fixed parameters. For the t-distribution for instance this is the degrees of freedom; most of the distributions have no parameters.
init	optional vector of initial values for the parameters.
scale	optional fixed value for the scale. If set to $\leq 0$ then the scale is estimated.
control	a list of control values, in the format produced by <code>survreg.control</code> . The default value is <code>survreg.control()</code>
model, x, y	flags to control what is returned. If any of these is true, then the model frame, the model matrix, and/or the vector of response times will be returned as components of the final result, with the same names as the flag arguments.
score	return the score vector. (This is expected to be zero upon successful convergence.)
robust	Use robust 'sandwich' standard errors, based on independence of individuals if there is no <code>cluster()</code> term in the formula, based on independence of clusters if there is.
...	other arguments which will be passed to <code>survreg.control</code> .

**Value**

an object of class `survreg` is returned.

**See Also**

**Examples**

```
# Fit an exponential model: the two fits are the same
survreg(Surv(futime, fustat) ~ ecog.ps + rx, ovarian, dist='weibull',
        scale=1)
survreg(Surv(futime, fustat) ~ ecog.ps + rx, ovarian,
        dist="exponential")

#
# A model with different baseline survival shapes for two groups, i.e.,
# two different scales
survreg(Surv(time, status) ~ ph.ecog + age + strata(sex), lung)

# There are multiple ways to parameterize a Weibull distribution. The survreg
# function imbeds it in a general location-scale family, which is a
# different parameterization than the rweibull function, and often leads
# to confusion.
# survreg's scale = 1/(rweibull shape)
# survreg's intercept = log(rweibull scale)
# For the log-likelihood all parameterizations lead to the same value.
y <- rweibull(1000, shape=2, scale=5)
survreg(Surv(y)~1, dist="weibull")

# Economists fit a model called 'tobit regression', which is a standard
# linear regression with Gaussian errors, and left censored data.
tobinfit <- survreg(Surv(durable, durable>0, type='left') ~ age + quant,
                  data=tobin, dist='gaussian')
```

---

survreg.control      *Package options for survreg and coxph*

---

### Description

This functions checks and packages the fitting options for [survreg](#)

### Usage

```
survreg.control(maxiter=30, rel.tolerance=1e-09,  
toler.chol=1e-10, iter.max, debug=0, outer.max=10)
```

### Arguments

maxiter	maximum number of iterations
rel.tolerance	relative tolerance to declare convergence
toler.chol	Tolerance to declare Cholesky decomposition singular
iter.max	same as maxiter
debug	print debugging information
outer.max	maximum number of outer iterations for choosing penalty parameters

### Value

A list with the same elements as the input

### See Also

[survreg](#)

---

survreg.distributions  
*Parametric Survival Distributions*

---

### Description

List of distributions for accelerated failure models. These are location-scale families for some transformation of time. The entry describes the cdf  $F$  and density  $f$  of a canonical member of the family.

### Usage

```
survreg.distributions
```

### Format

There are two basic formats, the first defines a distribution de novo, the second defines a new distribution in terms of an old one.

name:	name of distribution
variance:	function(parms) returning the variance (currently unused)
init(x,weights,...):	Function returning an initial estimate of the mean and variance (used for initial values in the iteration)
density(x,parms):	Function returning a matrix with columns $F$ , $1 - F$ , $f$ , $f'/f$ , $f''/f$
quantile(p,parms):	Quantile function
scale:	Optional fixed value for the scale parameter
parms:	Vector of default values and names for any additional parameters
deviance(y,scale,parms):	Function returning the deviance for a saturated model; used only for deviance residuals.

and to define one distribution in terms of another

name:	name of distribution
dist:	name of parent distribution
trans:	transformation (eg log)
dtrans:	derivative of transformation
itrans:	inverse of transformation
scale:	Optional fixed value for scale parameter

## Details

There are four basic distributions: `extreme`, `gaussian`, `logistic` and `t`. The last three are parametrised in the same way as the distributions already present in R. The extreme value cdf is

$$F = 1 - e^{-e^t}.$$

When the logarithm of survival time has one of the first three distributions we obtain respectively `weibull`, `lognormal`, and `loglogistic`. The location-scale parameterization of a Weibull distribution found in `survreg` is not the same as the parameterization of `rweibull`.

The other predefined distributions are defined in terms of these. The exponential and rayleigh distributions are Weibull distributions with fixed scale of 1 and 0.5 respectively, and `loggaussian` is a synonym for `lognormal`.

For speed parts of the three most commonly used distributions are hardcoded in C; for this reason the elements of `survreg.distributions` with names of "Extreme value", "Logistic" and "Gaussian" should not be modified. (The order of these in the list is not important, recognition is by name.) As an alternative to modifying `survreg.distributions` a new distribution can be specified as a separate list. This is the preferred method of addition and is illustrated below.

## Examples

```
# time transformation
survreg(Surv(time, status) ~ ph.ecog + sex, dist='weibull', data=lung)
# change the transformation to work in years
# intercept changes by log(365), everything else stays the same
```

```

my.weibull <- survreg.distributions$weibull
my.weibull$strans <- function(y) log(y/365)
my.weibull$itrans <- function(y) 365*exp(y)
survreg(Surv(time, status) ~ ph.ecog + sex, lung, dist=my.weibull)

# Weibull parametrisation
y<-rweibull(1000, shape=2, scale=5)
survreg(Surv(y)~1, dist="weibull")
# survreg parameters are scale=1/shape, intercept=log(scale)

# Cauchy fit
mycauchy <- list(name='Cauchy',
  init= function(x, weights, ...)
    c(median(x), mad(x)),
  density= function(x, parms) {
    temp <- 1/(1 + x^2)
    cbind(.5 + atan(temp)/pi, .5+ atan(-temp)/pi,
      temp/pi, -2 *x*temp, 2*temp^2*(4*x^2*temp -1))
  },
  quantile= function(p, parms) tan((p-.5)*pi),
  deviance= function(...) stop('deviance residuals not defined')
)
survreg(Surv(log(time), status) ~ ph.ecog + sex, lung, dist=mycauchy)

```

---

survreg.object

*Parametric Survival Model Object*

---

## Description

This class of objects is returned by the `survreg` function to represent a fitted parametric survival model. Objects of this class have methods for the functions `print`, `summary`, `predict`, and `residuals`.

## COMPONENTS

The following components must be included in a legitimate `survreg` object.

**coefficients** the coefficients of the `linear.predictors`, which multiply the columns of the model matrix. It does not include the estimate of error (sigma). The names of the coefficients are the names of the single-degree-of-freedom effects (the columns of the model matrix). If the model is over-determined there will be missing values in the coefficients corresponding to non-estimable coefficients.

**icoef** coefficients of the baseline model, which will contain the intercept and `log(scale)`, or multiple scale factors for a stratified model.

**var** the variance-covariance matrix for the parameters, including the `log(scale)` parameter(s).

**loglik** a vector of length 2, containing the log-likelihood for the baseline and full models.

**iter** the number of iterations required

**linear.predictors** the linear predictor for each subject.

**df** the degrees of freedom for the final model. For a penalized model this will be a vector with one element per term.

**scale** the scale factor(s), with length equal to the number of strata.

**idf** degrees of freedom for the initial model.

**means** a vector of the column means of the coefficient matrix.

**dist** the distribution used in the fit.

The object will also have the following components found in other model results (some are optional): `linear`, `predictors`, `weights`, `x`, `y`, `model`, `call`, `terms` and `formula`. See `lm`.

survregDtest	<i>Verify a survreg distribution</i>
--------------	--------------------------------------

---

### Description

This routine is called by `survreg` to verify that a distribution object is valid.

### Usage

```
survregDtest(dlist, verbose = F)
```

### Arguments

<code>dlist</code>	the list describing a survival distribution
<code>verbose</code>	return a simple TRUE/FALSE from the test for validity (the default), or a verbose description of any flaws.

### Details

If the `survreg` function rejects your user-supplied distribution as invalid, this routine will tell you why it did so.

### Value

TRUE if the distribution object passes the tests, and either FALSE or a vector of character strings if not.

### Author(s)

Terry Therneau

survSplit

*Split a survival data set at specified times*

---

**Description**

Given a survival data set and a set of specified cut times, split each record into multiple subrecords at each cut time. The new data set will be in ‘counting process’ format, with a start time, stop time, and event status for each record.

**Usage**

```
survSplit(data, cut, end, event, start, id = NULL, zero = 0,
  episode=NULL)
```

**Arguments**

data	data frame
cut	vector of timepoints to cut at
end	character string with name of event time variable
event	character string with name of censoring indicator
start	character string with name of start time variable (will be created if it does not exist)
id	character string with name of new id variable to create (optional)
zero	If <code>start</code> doesn't already exist, this is the time that the original records start. May be a vector or single value.
episode	character string with name of new episode variable (optional)

**Details**

The function also works when the original data are in counting-process format, but the `id` and `episode` options are of little use in this context.

**Value**

New, longer, data frame.

**See Also**

[Surv](#), [cut](#), [reshape](#)

**Examples**

```
aml3<-survSplit(aml,cut=c(5,10,50),end="time",start="start",
               event="status",episode="i")

summary(aml)
summary(aml3)

coxph(Surv(time,status)~x,data=aml)
## the same
coxph(Surv(start,time,status)~x,data=aml3)

aml4<-survSplit(aml3,cut=20,end="time",start="start", event="status")
coxph(Surv(start,time,status)~x,data=aml4)
```

---

tcut

*Factors for person-year calculations*

---

**Description**

Attaches categories for person-year calculations to a variable without losing the underlying continuous representation

**Usage**

```
tcut(x, breaks, labels, scale=1)
```

**Arguments**

x	numeric/date variable
breaks	breaks between categories, which are right-continuous
labels	labels for categories
scale	Multiply x and breaks by this.

**Value**

An object of class tcut

**See Also**

[cut](#), [pyears](#)

**Examples**

```

mdy.date <- function(m,d,y)
  as.Date(paste(ifelse(y<100, y+1900, y), m, d, sep='/'))
temp1 <- mdy.date(6,6,36)
temp2 <- mdy.date(6,6,55) # Now compare the results from person-years
#
temp.age <- tcut(temp2-temp1, floor(c(-1, (18:31 * 365.24))),
labels=c('0-18', paste(18:30, 19:31, sep='-')))
temp.yr <- tcut(temp2, mdy.date(1,1,1954:1965), labels=1954:1964)
temp.time <- 3700 #total days of fu
py1 <- pyears(temp.time ~ temp.age + temp.yr, scale=1) #output in days
py1

```

---

tobin

*Tobin's Tobit data*

---

**Description**

Economists fit a parametric censored data model called the 'tobit'. These data are from Tobin's original paper.

**Usage**

```
tobin
```

**Format**

A data frame with 20 observations on the following 3 variables.

**durable** Durable goods purchase

**age** Age in years

**quant** Liquidity ratio (x 1000)

**Source**

J Tobin (1958), Estimation of relationships for limited dependent variables. *Econometrica* **26**, 24–36.

**Examples**

```

tfit <- survreg(Surv(durable, durable>0, type='left') ~age + quant,
               data=tobin, dist='gaussian')

predict(tfit,type="response")

```

---

`untangle.specials` *Help Process the 'specials' Argument of the 'terms' Function.*

---

### Description

Given a `terms` structure and a desired special name, this returns an index appropriate for subscripting the `terms` structure and another appropriate for the data frame.

### Usage

```
untangle.specials(tt, special, order=1)
```

### Arguments

<code>tt</code>	a <code>terms</code> object.
<code>special</code>	the name of a special function, presumably used in the <code>terms</code> object.
<code>order</code>	the order of the desired terms. If set to 2, interactions with the special function will be included.

### Value

a list with two components:

<code>vars</code>	a vector of variable names, as would be found in the data frame, of the specials.
<code>terms</code>	a numeric vector, suitable for subscripting the <code>terms</code> structure, that indexes the terms in the expanded model formula which involve the special.

### Examples

```
formula<-Surv(tt,ss)~x+z*strata(id)
tms<-terms(formula,specials="strata")
## the specials attribute
attr(tms,"specials")
## main effects
untangle.specials(tms,"strata")
## and interactions
untangle.specials(tms,"strata",order=1:2)
```

---

`veteran`

*Veterans' Administration Lung Cancer study*

---

### Description

Randomised trial of two treatment regimens for lung cancer. This is a standard survival analysis data set.

### Usage

```
veteran
```

### Format

trt: 1=standard 2=test  
celltype: 1=squamous, 2=smallcell, 3=adeno, 4=large  
time: survival time  
status: censoring status  
karno: Karnofsky performance score (100=good)  
diagtime: months from diagnosis to randomisation  
age: in years  
prior: prior therapy 0=no, 1=yes

## Chapter 26

# The `tcltk` package

---

`tcltk-package`      *Tcl/Tk Interface*

---

### Description

Interface and language bindings to Tcl/Tk GUI elements.

### Details

This package provides access to the platform-independent Tcl scripting language and Tk GUI elements. See [TkWidgets](#) for a list of supported widgets, [TkWidgetcmds](#) for commands to work with them, and references in those files for more.

The Tcl/Tk documentation is in the system man pages.

For a complete list of functions, use `ls ("package:tcltk")`.

Note that Tk will not be initialized if there is no `DISPLAY` variable set, but Tcl can still be used. This is most useful to allow the loading of a package which depends on `tcltk` in a session that does not actually use it (e.g. during installation).

Maintainer: R Core Team <[R-core@r-project.org](mailto:R-core@r-project.org)>

---

`TclInterface`      *Low-level Tcl/Tk Interface*

---

### Description

These functions and variables provide the basic glue between R and the Tcl interpreter and Tk GUI toolkit. Tk windows may be represented via R objects. Tcl variables can be accessed via objects of class `tclVar` and the C level interface to Tcl objects is accessed via objects of class `tclObj`.

**Usage**

```

.Tcl(...)
.Tcl.objv(objv)
.Tcl.args(...)
.Tcl.args.objv(...)
.Tcl.callback(...)
.Tk.ID(win)
.Tk.newwin(ID)
.Tk.subwin(parent)
.TkRoot

tkdestroy(win)
is.tkwin(x)

tclvalue(x)
tclvalue(x) <- value

tclVar(init="")
## S3 method for class 'tclVar':
as.character(x, ...)
## S3 method for class 'tclVar':
tclvalue(x)
## S3 replacement method for class 'tclVar':
tclvalue(x) <- value

tclArray()
## S3 method for class 'tclArray':
x[[...]]
## S3 replacement method for class 'tclArray':
x[[...]] <- value
## S3 method for class 'tclArray':
x$i
## S3 replacement method for class 'tclArray':
x$i <- value

## S3 method for class 'tclArray':
names(x)
## S3 method for class 'tclArray':
length(x)

tclObj(x)
tclObj(x) <- value
## S3 method for class 'tclVar':
tclObj(x)
## S3 replacement method for class 'tclVar':
tclObj(x) <- value

as.tclObj(x, drop=FALSE)
is.tclObj(x)

## S3 method for class 'tclObj':
as.character(x, ...)

```

```

## S3 method for class 'tclObj':
as.integer(x, ...)
## S3 method for class 'tclObj':
as.double(x, ...)
## S3 method for class 'tclObj':
as.logical(x, ...)
## S3 method for class 'tclObj':
as.raw(x, ...)
## S3 method for class 'tclObj':
tclvalue(x)

## Default S3 method:
tclvalue(x)
## Default S3 method:
tclvalue(x) <- value

addTclPath(path = ".")
tclRequire(package, warn = TRUE)

```

### Arguments

objv	a named vector of Tcl objects
win	a window structure
x	an object
i	character or (unquoted) name
drop	logical. Indicates whether a single-element vector should be made into a simple Tcl object or a list of length one
value	For <code>tclvalue</code> assignments, a character string. For <code>tclObj</code> assignments, an object of class <code>tclObj</code>
ID	a window ID
parent	a window which becomes the parent of the resulting window
path	path to a directory containing Tcl packages
package	a Tcl package name
warn	logical. Warn if not found?
...	Additional arguments. See below.
init	initialization value

### Details

Many of these functions are not intended for general use but are used internally by the commands that create and manipulate Tk widgets and Tcl objects. At the lowest level `.Tcl` sends a command as a text string to the Tcl interpreter and returns the result as an object of class `tclObj` (see below). A newer variant `.Tcl.objv` accepts arguments in the form of a named list of `tclObj` objects.

`.Tcl.args` converts an R argument list of `tag=value` pairs to the Tcl `-option value` style, thus enabling a simple translation between the two languages. To send a value with no preceding option flag to Tcl, just use an untagged argument. In the rare case one needs an option with no subsequent value `tag=NULL` can be used. Most values are just converted to character mode and

inserted in the command string, but window objects are passed using their ID string, and callbacks are passed via the result of `.Tcl.callback`. Tags are converted to option flags simply by prepending a `-`

`.Tcl.args.objv` serves a similar purpose as `.Tcl.args` but produces a list of `tclObj` objects suitable for passing to `.Tcl.objv`. The names of the list are converted to Tcl option style internally by `.Tcl.objv`.

Callbacks can be either *atomic callbacks* handled by `.Tcl.callback` or expressions. An expression is treated as a list of atomic callbacks, with the following exceptions: if an element is a name, it is first evaluated in the callers frame, and likewise if it is an explicit function definition; the `break` expression is translated directly to the Tcl counterpart. `.Tcl.callback` converts R functions and unevaluated calls to Tcl command strings. The argument must be either a function closure or an object of mode `"call"` followed by an environment. The return value in the first case is of the form `R_call 0x408b94d4` in which the hexadecimal number is the memory address of the function. In the second case it will be of the form `R_call_lang 0x8a95904 0x819bfd0`. For expressions, a sequence of similar items is generated, separated by semicolons. `.Tcl.args` takes special precautions to ensure that functions or calls will continue to exist at the specified address by assigning the callback into the relevant window environment (see below).

Tk windows are represented as objects of class `tkwin` which are lists containing a `ID` field and an `env` field which is an R environments, enclosed in the global environment. The value of the `ID` field is identical to the Tk window name. The `env` environment contains a `parent` variable and a `num.subwin` variable. If the window obtains sub-windows and callbacks, they are added as variables to the environment. `.TkRoot` is the top window with ID `."`; this window is not displayed in order to avoid ill effects of closing it via window manager controls. The `parent` variable is undefined for `.TkRoot`.

`.Tk.ID` extracts the ID of a window, `.Tk.newwin` creates a new window environment with a given ID and `.Tk.subwin` creates a new window which is a sub-window of a given parent window.

`tkdestroy` destroys a window and also removes the reference to a window from its parent.

`is.tkwin` can be used to test whether a given object is a window environment.

`tclVar` creates a new Tcl variable and initializes it to `init`. An R object of class `tclVar` is created to represent it. Using `as.character` on the object returns the Tcl variable name. Accessing the Tcl variable from R is done using the `tclvalue` function, which can also occur on the left-hand side of assignments. If `tclvalue` is passed an argument which is not a `tclVar` object, then it will assume that it is a character string explicitly naming global Tcl variable. Tcl variables created by `tclVar` are uniquely named and automatically unset by the garbage collector when the representing object is no longer in use.

`tclArray` creates a new Tcl array and initializes it to the empty array. An R object of class `tclArray` and inheriting from class `tclVar` is created to represent it. You can access elements of the Tcl array using indexing with `[]` or `$`, which also allow replacement forms. Notice that Tcl arrays are associative by nature and hence unordered; indexing with a numeric index `i` refers to the element with the *name* `as.character(i)`. Multiple indices are pasted together separated by commas to form a single name. You can query the length and the set of names in an array using methods for `length` and `names`, respectively; these cannot meaningfully be set so assignment forms exist only to print an error message.

It is possible to access Tcl's 'dual-ported' objects directly, thus avoiding parsing and deparsing of their string representation. This works by using objects of class `tclObj`. The string representation of such objects can be extracted (but not set) using `tclvalue` and conversion to vectors of mode `"character"`, `"double"`, `"integer"`, `"logical"`. Conversely, such vectors can be converted using `as.tclObj`. There is an ambiguity as to what should happen for length one vectors, controlled by the `drop` argument; there are cases where the distinction matters to Tcl, although

mostly it treats them equivalently. Notice that `tclvalue` and `as.character` differ on an object whose string representation has embedded spaces, the former is sometimes to be preferred, in particular when applied to the result of `tclread`, `tkgetOpenFile`, and similar functions. The `as.raw` method returns a raw vector or a list of raw vectors and can be used to return binary data from Tcl.

The object behind a `tclVar` object is extracted using `tclObj(x)` which also allows an assignment form, in which the right hand side of the assignment is automatically converted using `as.tclObj`. There is a `print` method for `tclObj` objects; it prints `<Tcl>` followed by the string representation of the object. Notice that `as.character` on a `tclVar` object is the *name* of the corresponding Tcl variable and not the value.

Tcl packages can be loaded with `tclRequire`; it may be necessary to add the directory where they are found to the Tcl search path with `addTclPath`. The return value is a class `"tclObj"` object if it succeeds, or `FALSE` if it fails (when a warning is issued).

### Note

Strings containing unbalanced braces are currently not handled well in many circumstances.

### See Also

[TkWidgets](#), [TkCommands](#), [TkWidgetcmds](#).

`capabilities("tcltk")` to see if Tcl/Tk support was compiled into this build of R.

### Examples

```
## Not run:
## These cannot be run by example() but should be OK when pasted
## into an interactive R session with the tcltk package loaded
.Tcl("format \"%s\n\" \"Hello, World!\")
f <- function()cat("HI!\n")
.Tcl.callback(f)
.Tcl.args(text="Push!", command=f) # NB: Different address

xyzy <- tclVar(7913)
tclvalue(xyzy)
tclvalue(xyzy) <- "foo"
as.character(xyzy)
tcl("set", as.character(xyzy))

top <- tktoplevel() # a Tk widget, see Tk-widgets
ls(envir=top$env, all=TRUE)
ls(envir=.TkRoot$env, all=TRUE) # .Tcl.args put a callback ref in here

## End(Not run)
```

---

tclServiceMode	<i>Allow Tcl events to be serviced or not</i>
----------------	---

---

### Description

This function controls or reports on the Tcl service mode, i.e. whether Tcl will respond to events.

**Usage**

```
tclServiceMode(on = NULL)
```

**Arguments**

`on` (logical) Whether event servicing is turned on.

**Details**

If called with `on == NULL` (the default), no change is made.

Note that this blocks all Tcl/Tk activity, including for widgets from other packages. It may be better to manage mapping of windows individually.

**Value**

The value of the Tcl service mode before the call.

**Examples**

```
## see demo(tkcanvas) for an example
## Not run:
  oldmode <- tclServiceMode(FALSE)
  # Do some work to create a nice picture.  Nothing will be displayed until...
  tclServiceMode(oldmode)

## End(Not run)
## another idea is to use tkwm.withdraw() ... tkwm.deiconify()
```

---

TkCommands

*Tk non-widget commands*

---

**Description**

These functions interface to Tk non-widget commands, such as the window manager interface commands and the geometry managers.

**Usage**

```
tcl(...)
tktitle(x)

tktitle(x) <- value

tkbell(...)
tkbind(...)
tkbindtags(...)
tkfocus(...)
tklower(...)
tkraise(...)

tkclipboard.append(...)
tkclipboard.clear(...)
```

```
tkevent.add(...)
tkevent.delete(...)
tkevent.generate(...)
tkevent.info(...)

tkfont.actual(...)
tkfont.configure(...)
tkfont.create(...)
tkfont.delete(...)
tkfont.families(...)
tkfont.measure(...)
tkfont.metrics(...)
tkfont.names(...)

tkgrab(...)
tkgrab.current(...)
tkgrab.release(...)
tkgrab.set(...)
tkgrab.status(...)

tkimage.cget(...)
tkimage.configure(...)
tkimage.create(...)
tkimage.names(...)

## NB: some widgets also have a selection.clear command, hence the "X".

tkXselection.clear(...)
tkXselection.get(...)
tkXselection.handle(...)
tkXselection.own(...)

tkwait.variable(...)
tkwait.visibility(...)
tkwait.window(...)

## winfo actually has a large number of subcommands, but it's rarely
## used, so use tkwinfo("atom", ...) etc. instead.

tkwinfo(...)

# Window manager interface

tkwm.aspect(...)
tkwm.client(...)
tkwm.colormapwindows(...)
tkwm.command(...)
tkwm.deiconify(...)
tkwm.focusmodel(...)
tkwm.frame(...)
tkwm.geometry(...)
```

```
tkwm.grid(...)
tkwm.group(...)
tkwm.iconbitmap(...)
tkwm.iconify(...)
tkwm.iconmask(...)
tkwm.iconname(...)
tkwm.iconposition(...)
tkwm.iconwindow(...)
tkwm.maxsize(...)
tkwm.minsize(...)

tkwm.positionfrom(...)
tkwm.protocol(...)
tkwm.resizable(...)
tkwm.sizefrom(...)
tkwm.state(...)
tkwm.title(...)
tkwm.transient(...)
tkwm.withdraw(...)
```

### ### Geometry managers

```
tkgrid(...)
tkgrid.bbox(...)
tkgrid.columnconfigure(...)
tkgrid.configure(...)
tkgrid.forget(...)
tkgrid.info(...)
tkgrid.location(...)
tkgrid.propagate(...)
tkgrid.rowconfigure(...)
tkgrid.remove(...)
tkgrid.size(...)
tkgrid.slaves(...)
```

```
tkpack(...)
tkpack.configure(...)
tkpack.forget(...)
tkpack.info(...)
tkpack.propagate(...)
tkpack.slaves(...)
```

```
tkplace(...)
tkplace.configure(...)
tkplace.forget(...)
tkplace.info(...)
tkplace.slaves(...)
```

```
## Standard dialogs
tkgetOpenFile(...)
tkgetSaveFile(...)
```

```

tkchooseDirectory(...)
tkmessageBox(...)
tkdialog(...)
tkpopup(...)

## File handling functions
tclfile.tail(...)
tclfile.dir(...)
tclopen(...)
tclclose(...)
tclputs(...)
tclread(...)

```

### Arguments

x	A window object
value	For <code>tktitle</code> assignments, a character string.
...	Handled via <code>.Tcl.args</code>

### Details

`tcl` provides a generic interface to calling any Tk or Tcl command by simply running `.Tcl.args.objv` on the argument list and passing the result to `.Tcl.objv`. Most of the other commands simply call `tcl` with a particular first argument and sometimes also a second argument giving the subcommand.

`tktitle` and its assignment form provides an alternate interface to Tk's `wm title`

There are far too many of these commands to describe them and their arguments in full. Please refer to the Tcl/Tk documentation for details. With a few exceptions, the pattern is that Tk subcommands like `pack` `configure` are converted to function names like `tkpack.configure`, and Tcl subcommands are like `tclfile.dir`.

### See Also

[TclInterface](#), [TkWidgets](#), [TkWidgetcmds](#)

### Examples

```

## Not run:
## These cannot be run by examples() but should be OK when pasted
## into an interactive R session with the tcltk package loaded

tt <- tktoplevel()
tkpack(l1<-tklabel(tt,text="Heave"), l2<-tklabel(tt,text="Ho"))
tkpack.configure(l1, side="left")

## Try stretching the window and then

tkdestroy(tt)

## End(Not run)

```

---

`tkpager`*Page file using Tk text widget*

---

**Description**

This plugs into `file.show`, showing files in separate windows.

**Usage**

```
tkpager(file, header, title, delete.file)
```

**Arguments**

<code>file</code>	character vector containing the names of the files to be displayed
<code>header</code>	headers to use for each file
<code>title</code>	common title to use for the window(s). Pasted together with the header to form actual window title.
<code>delete.file</code>	logical. Should file(s) be deleted after display?

**Note**

The "`\b_`" string used for underlining is currently quietly removed. The font and background colour are currently hardcoded to Courier and gray90.

**See Also**

[file.show](#)

---

`tkProgressBar`*Progress Bars via Tk*

---

**Description**

Put up a Tk progress bar widget.

**Usage**

```
tkProgressBar(title = "R progress bar", label = "",
              min = 0, max = 1, initial = 0, width = 300)

getTkProgressBar(pb)
setTkProgressBar(pb, value, title = NULL, label = NULL)
## S3 method for class 'tkProgressBar':
close(con, ...)
```

## Arguments

<code>title, label</code>	character strings, giving the window title and the label on the dialog box respectively.
<code>min, max</code>	(finite) numeric values for the extremes of the progress bar.
<code>initial, value</code>	initial or new value for the progress bar.
<code>width</code>	the width of the progress bar in pixels: the dialog box will be 40 pixels wider (plus frame).
<code>pb, con</code>	an object of class "tkProgressBar".
<code>...</code>	for consistency with the generic.

## Details

`tkProgressBar` will display a widget containing a label and progress bar.

`setTkProgressBar` will update the value and for non-NULL values, the title and label (provided there was one when the widget was created). Missing (NA) and out-of-range values of `value` will be (silently) ignored.

The progress bar should be `closed` when finished with.

This will use the `ttk::progressbar` widget for Tk version 8.5 or later, otherwise R's copy of `BWidget's progressbar`.

## Value

For `tkProgressBar` an object of class "tkProgressBar".

For `getTkProgressBar` and `setTkProgressBar`, a length-one numeric vector giving the previous value (invisibly for `setTkProgressBar`).

## See Also

[txtProgressBar](#)

## Examples

```
pb <- tkProgressBar("test progress bar", "Some information in %",
                   0, 100, 50)
Sys.sleep(0.5)
u <- c(0, sort(runif(20, 0, 100)), 100)
for(i in u) {
  Sys.sleep(0.1)
  info <- sprintf("%d%% done", round(i))
  setTkProgressBar(pb, i, sprintf("test (%s)", info), info)
}
Sys.sleep(5)
close(pb)
```

---

tkStartGUI	<i>Tcl/Tk GUI startup</i>
------------	---------------------------

---

**Description**

Starts up the Tcl/Tk GUI

**Usage**

```
tkStartGUI()
```

**Details**

Starts a GUI console implemented via a Tk text widget. This should probably be called at most once per session. Also redefines the file pager (as used by `help()`) to be the Tk pager.

**Note**

`tkStartGUI()` saves its evaluation environment as `.GUIenv`. This means that the user interface elements can be accessed in order to extend the interface. The three main objects are named `Term`, `Menu`, and `Toolbar`, and the various submenus and callback functions can be seen with `ls(envir=.GUIenv)`.

Peter Dalgaard

---

TkWidgetcmds	<i>Tk widget commands</i>
--------------	---------------------------

---

**Description**

These functions interface to Tk widget commands.

**Usage**

```
tkactivate(widget, ...)  
tkadd(widget, ...)  
tkaddtag(widget, ...)  
tkbbox(widget, ...)  
tkcanvasx(widget, ...)  
tkcanvasy(widget, ...)  
tkcget(widget, ...)  
tkcompare(widget, ...)  
tkconfigure(widget, ...)  
tkcoords(widget, ...)  
tkcreate(widget, ...)  
tkcurselection(widget, ...)  
tkdchars(widget, ...)  
tkdebug(widget, ...)
```

```
tkdelete(widget, ...)
tkdelta(widget, ...)
tkdeselect(widget, ...)
tkdlineinfo(widget, ...)
tkdtag(widget, ...)
tkdump(widget, ...)
tkentrycget(widget, ...)
tkentryconfigure(widget, ...)
tkfind(widget, ...)
tkflash(widget, ...)
tkfraction(widget, ...)
tkget(widget, ...)
tkgettags(widget, ...)
tkicursor(widget, ...)
tkidentify(widget, ...)
tkindex(widget, ...)
tkinsert(widget, ...)
tkinvoke(widget, ...)
tkitembind(widget, ...)
tkitemcget(widget, ...)

tkselection.from(widget, ...)
tkselection.includes(widget, ...)
tkselection.present(widget, ...)
tkselection.range(widget, ...)
tkselection.set(widget, ...)
tkselection.to(widget, ...)
tkset(widget, ...)
tksize(widget, ...)
```

```

tktoggle(widget, ...)
tktag.add(widget, ...)
tktag.bind(widget, ...)
tktag.cget(widget, ...)
tktag.configure(widget, ...)
tktag.delete(widget, ...)
tktag.lower(widget, ...)
tktag.names(widget, ...)
tktag.nextrange(widget, ...)
tktag.prevrange(widget, ...)
tktag.raise(widget, ...)
tktag.ranges(widget, ...)
tktag.remove(widget, ...)
tktype(widget, ...)
tkunpost(widget, ...)
tkwindow.cget(widget, ...)
tkwindow.configure(widget, ...)
tkwindow.create(widget, ...)
tkwindow.names(widget, ...)
tkxview(widget, ...)
tkxview.moveto(widget, ...)
tkxview.scroll(widget, ...)
tkyposition(widget, ...)
tkyview(widget, ...)
tkyview.moveto(widget, ...)
tkyview.scroll(widget, ...)

```

### Arguments

widget	The widget this applies to
...	Handled via <code>.Tcl.args</code>

### Details

There are far too many of these commands to describe them and their arguments in full. Please refer to the Tcl/Tk documentation for details. Except for a few exceptions, the pattern is that Tcl widget commands possibly with subcommands like `.a.b selection clear` are converted to function names like `tkselection.clear` and the widget is given as the first argument.

### See Also

[TclInterface](#), [TkWidgets](#), [TkCommands](#)

### Examples

```

## Not run:
## These cannot be run by examples() but should be OK when pasted
## into an interactive R session with the tcltk package loaded

tt <- tktoplevel()
tkpack(txt.w <- tktext(tt))
tkinsert(txt.w, "0.0", "plot(1:10)")

# callback function

```

```
eval.txt <- function()  
  eval(parse(text=tclvalue(tkget(txt.w, "0.0", "end"))))  
tkpack(but.w <- tkbutton(tt,text="Submit", command=eval.txt))  
  
## Try pressing the button, edit the text and when finished:  
  
tkdestroy(tt)  
  
## End(Not run)
```

---

TkWidgets

*Tk widgets*

---

## Description

Create Tk widgets and associated R objects.

## Usage

```
tkwidget(parent, type, ...)  
  
tkbutton(parent, ...)  
tkcanvas(parent, ...)  
tkcheckbutton(parent, ...)  
tkentry(parent, ...)  
ttkentry(parent, ...)  
tkframe(parent, ...)  
tklabel(parent, ...)  
tklistbox(parent, ...)  
tkmenu(parent, ...)  
tkmenubutton(parent, ...)  
tkmessage(parent, ...)  
tkradiobutton(parent, ...)  
tkscale(parent, ...)  
tkscrollbar(parent, ...)  
tktext(parent, ...)  
tktoplevel(parent = .TkRoot, ...)  
  
ttkbutton(parent, ...)  
ttkcheckbutton(parent, ...)  
ttkcombobox(parent, ...)  
ttkframe(parent, ...)  
ttkimage(parent, ...)  
ttklabel(parent, ...)  
ttklabelframe(parent, ...)  
ttkmenubutton(parent, ...)  
ttknotebook(parent, ...)  
ttkpanedwindow(parent, ...)  
ttkprogressbar(parent, ...)  
ttkradiobutton(parent, ...)  
ttkscrollbar(parent, ...)
```

```
ttkseparator(parent, ...)
ttksizegrip(parent, ...)
ttktreeview(parent, ...)
```

### Arguments

parent	Parent of widget window.
type	string describing the type of widget desired.
...	handled via <code>.Tcl.args</code> .

### Details

These functions create Tk widgets. `tkwidget` creates a widget of a given type, the others simply call `tkwidget` with the respective `type` argument.

The functions starting `ttk` are for the themed widget set for Tk 8.5 or later. A tutorial can be found at <http://www.tkdocks.com>.

It is not possible to describe the widgets and their arguments in full. Please refer to the Tcl/Tk documentation.

### See Also

[TclInterface](#), [TkCommands](#), [TkWidgetcmds](#)

### Examples

```
## Not run:
## These cannot be run by examples() but should be OK when pasted
## into an interactive R session with the tcltk package loaded

tt <- tktoplevel()
label.widget <- tklabel(tt, text="Hello, World!")
button.widget <- tkbutton(tt, text="Push",
                          command=function() cat ("OW!\n"))
tkpack(label.widget, button.widget) # geometry manager
                                   # see Tk-commands

## Push the button and then...

tkdestroy(tt)

## test for themed widgets
if(as.character(tcl("info", "tclversion")) >= "8.5") {
  # make use of themed widgets
  # list themes
  as.character(tcl("ttk::style", "theme", "names"))
  # select a theme -- here pre-XP windows
  tcl("ttk::style", "theme use", "winnative")
} else {
  # use Tk 8.0 widgets
}

## End(Not run)
```

---

tk\_choose.dir      *Choose a Folder Interactively*

---

**Description**

Use a Tk widget to choose a directory interactively.

**Usage**

```
tk_choose.dir(default = "", caption = "Select directory")
```

**Arguments**

default	which directory to show initially.
caption	the caption on the selection dialog.

**Value**

A length-one character vector, character NA if 'Cancel' was selected.

**See Also**

[tk\\_choose.files](#)

**Examples**

```
## Not run:
tk_choose.dir(getwd(), "Choose a suitable folder")

## End(Not run)
```

---

tk\_choose.files      *Choose a List of Files Interactively*

---

**Description**

Use a Tk file dialog to choose a list of zero or more files interactively.

**Usage**

```
tk_choose.files(default = "", caption = "Select files",
                multi = TRUE, filters = NULL, index = 1)
```

**Arguments**

default	which filename to show initially.
caption	the caption on the file selection dialog.
multi	whether to allow multiple files to be selected.
filters	two-column character matrix of filename filters.
index	unused.

**Details**

Unlike `file.choose`, `tk_choose.files` will always attempt to return a character vector giving a list of files. If the user cancels the dialog, then zero files are returned, whereas `file.choose` would signal an error.

The format of `filters` can be seen from the example. File patterns are specified via extensions, with "\*" meaning any file, and "" any file without an extension (a filename not containing a period). (Other forms may work on specific platforms.) Note that the way to have multiple extensions for one file type is to have multiple rows with the same name in the first column, and that whether the extensions are named in file chooser widget is platform-specific. **The format may change before release.**

**Value**

A character vector giving zero or more file paths.

**Note**

A bug in Tk 8.5.0–8.5.4 prevented multiple selections being used.

**See Also**

`file.choose`, `tk_choose.dir`

**Examples**

```
Filters <- matrix(c("R code", ".R", "R code", ".s",
                  "Text", ".txt", "All files", "*"),
                4, 2, byrow = TRUE)
Filters
if(interactive()) tk_choose.files(filter = Filters)
```

---

tk\_messageBox

*Tk Message Box*

---

**Description**

An implementation of a generic message box using Tk

**Usage**

```
tk_messageBox(type = c("ok", "okcancel", "yesno", "yesnocancel",
                      "retrycancel", "aburtretrycancel"),
             message, caption = "", default = "", ...)
```

**Arguments**

<code>type</code>	character. The type of dialog box. It will have the buttons implied by its name.
<code>message</code>	character. The information field of the dialog box.
<code>caption</code>	the caption on the widget displayed.
<code>default</code>	character. The name of the button to be used as the default.
<code>...</code>	additional named arguments to be passed to the Tk function of this name. An example is <code>icon="warning"</code> .

**Value**

A character string giving the name of the button pressed.

**See Also**

[tkmessageBox](#) for a 'raw' interface.

---

tk\_select.list      *Select Items from a List*

---

**Description**

Select item(s) from a character vector using a Tk listbox.

**Usage**

```
tk_select.list(choices, preselect = NULL, multiple = FALSE, title = NULL)
```

**Arguments**

choices	a character vector of items.
preselect	a character vector, or NULL. If non-null and if the string(s) appear in the list, the item(s) are selected initially.
multiple	logical: can more than one item be selected?
title	optional character string for window title, or NULL for no title.

**Details**

This is a version of [select.list](#) implemented as a Tk list box plus OK and Cancel buttons. There will be a scrollbar if the list is too long to fit comfortably on the screen.

The dialog box is *modal*, so a selection must be made or cancelled before the R session can proceed. As from R 2.10.1 double-clicking on an item is equivalent to selecting it and then clicking OK.

If Tk is version 8.5 or later, themed widgets will be used.

**Value**

A character vector of selected items. If `multiple` is false and no item was selected (or Cancel was used), "" is returned. If `multiple` is true and no item was selected (or Cancel was used) then a character vector of length 0 is returned.

**See Also**

[select.list](#) (a text version except on Windows and the Mac OS X GUI), [menu](#) (whose `graphics=TRUE` mode uses this on most Unix-alikes).
